# Exploring alternate realities: counterfactual approaches for extreme loss modelling

## *The case of the 2016 Alberta Wildfires*

GIRO 2016 workshop D9

Junaid Seria  
**SCOR**  
The Art & Science of Risk

# Key messages

## 1. The Nat Cat Validation Working Party's first phase of work is complete

- a report detailing the validation framework proposed including case studies will be published in Spring 2017.

## 2. Embedding Solvency II in Catastrophe Risk Management is challenging for various reasons

- process uncertainty, model complexity, SII requirements, organisational design and resource constraints – we need to get back to basics and make validation more relevant to business

## 3. *Counterfactual analysis*, a scenario testing technique we explain and illustrate via a case study helps us do this:

- it's easy to implement, stimulates engagement because it is rooted in history and achieves the goal of increasing risk awareness amongst decision-makers
- Actuaries with no inquisitiveness / curiosity need not apply

## Comprehensive Scope of Test Topics

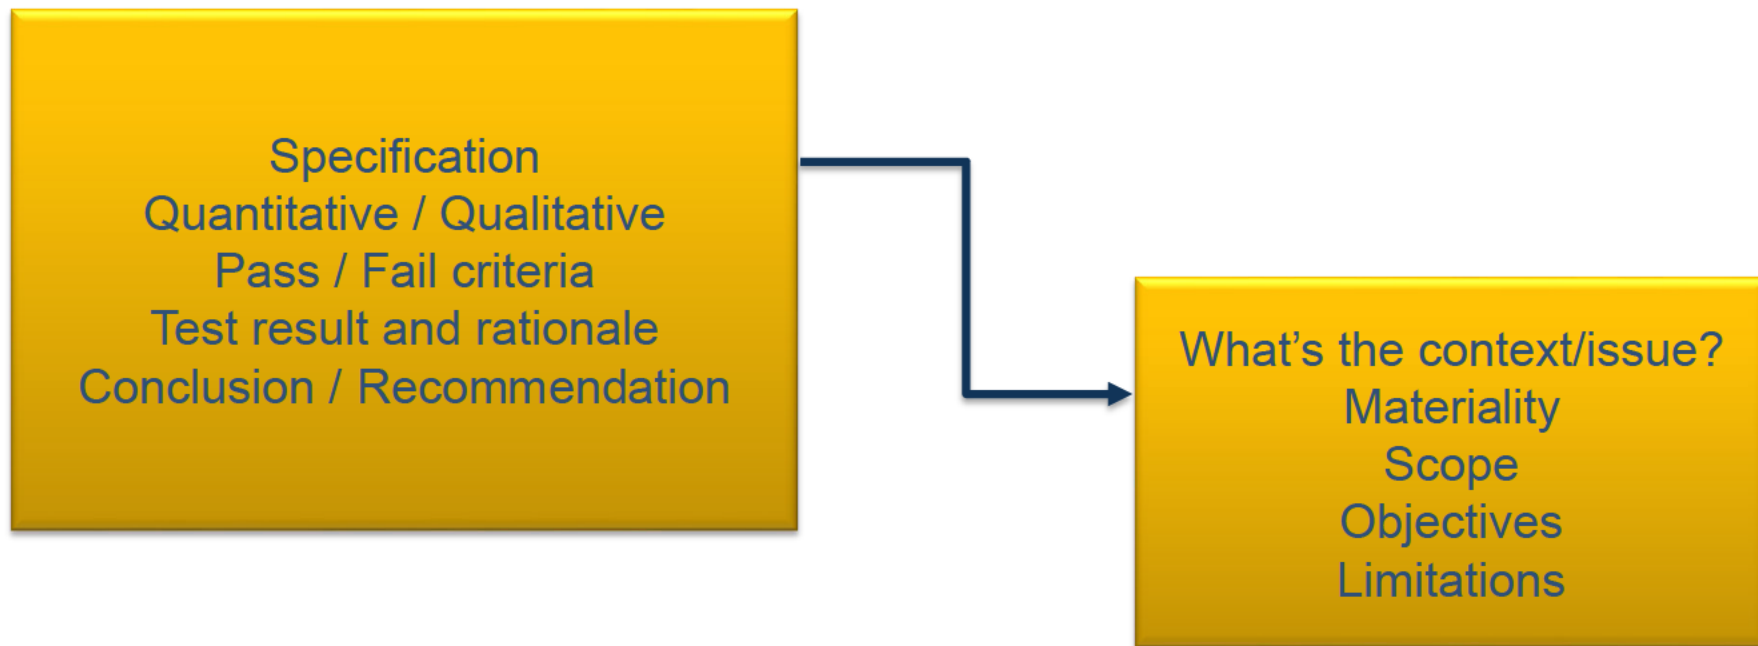

Institute  
and Faculty  
of Actuaries

# Nat Cat Validation Working Party

## Consistent Unbiased Test Structure

# Nat Cat Validation Working Party

## Range of Test Tools and (target) Conclusions

- Analysis of change
- Back-testing / As-if testing
- Benchmark testing
- (Reverse) Stress testing
- Scenario testing
- Sensitivity testing
- Functional testing
- Risk attribution testing

Resilient to shocks, both historical and hypothetical

“Complete” (material risks)  
Represents range of possible outcomes  
Serves capital and pricing functions  
Consistent model response

Stable results (consistent run times)  
Validates well against observed history  
Can replicate important vendor methods

Institute  
and Faculty  
of Actuaries

# Case Studies

## Demonstrate application of the framework

1. **Back-test:** validate third-party vendor UK windstorm cat model vulnerability curves against internal claims history
2. **Sensitivity test:** investigate sensitivity of assumptions made about earthquake seismic resistance of insured property in Taiwan in order to decide whether or not to load for corrupt building practice
3. **Stress test:** assess whether range of events in the stochastic catalogue includes plausible stress scenarios
4. **Reverse stress test:** Validate Cat Risk loss distribution against most probable stresses that would threaten viability of the risk carrier
5. **Benchmark test:** Compare internal calibration of clustering of European windstorm events against alternative vendor approaches

Institute  
and Faculty  
of Actuaries

# Key messages

1. The Nat Cat Validation Working Party's first phase of work is complete
2. **Embedding Solvency II in Catastrophe Risk Management is challenging for various reasons**
  - process uncertainty, model complexity, SII requirements, organisational design and resource constraints – we need to get back to basics and make validation more relevant to business
3. *Counterfactual analysis*, a scenario testing technique we explain and illustrate via a case study helps us do this

# Challenges to embedding Solvency II

1. **Objective:** help senior management / Board gain comfort over the modelling methods and results used in catastrophe risk management in support of key decisions – *help them make sense of the numbers*
2. **Challenges:** complexity of processes modelled, modelling techniques, overly detailed validation, automated processes devoid of fundamental analysis
3. **Implications:** Risk insights either not revealed or where revealed do not always find their way to those at the front-line: e.g., underwriters and reinsurance departments

## 4. **Guidance:**

- less regulatory “tick-box” exercises
- more focus on application in decision-making – e.g., portfolio / capital management, pricing, exposure monitoring and business planning
- Dynamic validation cycles to keep pace with decision-making

Institute  
and Faculty  
of Actuaries

# Key messages

1. The Nat Cat Validation Working Party's first phase of work is complete
2. Embedding Solvency II in Catastrophe Risk Management is challenging for various reasons
  - process uncertainty, model complexity, SII requirements, organisational design and resource constraints – we need to get back to basics and make validation more relevant to business
3. ***Counterfactual analysis*, a scenario testing technique we explain and illustrate via a case study helps us do this**

# Counterfactual Analysis

## Goals

1. Understand counterfactual analysis as a validation tool
2. Understand how to apply the approach as illustrated in the context of the 2016 Fort McMurray wildfires
3. Understand the benefits of this approach

# Counterfactual Analysis

## Introduction

- Recognises that what happened was not inevitable, but is only one realisation of numerous alternative possibilities
- Allows us to access more data points: **losses are rare, near misses are common**
- We consider the historical record and ask:
  - *what if things had gone wrong? (in the case of near-misses)*
  - *what if things had turned for the worse? (in the case of a loss event)*
- More relevant for region-perils not modelled by third-party vendor cat models

of Actuaries

# Counterfactual Analysis

## Case Study: 2016 Fort McMurray wildfires

- **Case Study:** We consider the wildfires that affected Fort McMurray, in Alberta Canada in early May 2016
- **Facts:** most costly natural disaster in Canada to date, surpassing the 2013 Alberta floods, and indeed the costliest wildfire event in the world

According to data from Property Claim Services (PCS), Alberta wildfires are estimated to cost the insurance industry US\$3.5bn, at the lower end of AIR Worldwide's loss forecast range of US\$3.4bn – US\$6.9bn and Morgan Stanley's estimated loss range of US\$3bn - US\$7bn. The Insurance Bureau of Canada reported a lower estimate of \$2.73bn on 7 July 2016. These estimates exceed previous insured loss records of US\$1.9bn for the 2013 Alberta floods and US\$1.6bn for the 1998 Quebec ice storm (Sigma reports)

Institute  
and Faculty  
of Actuaries

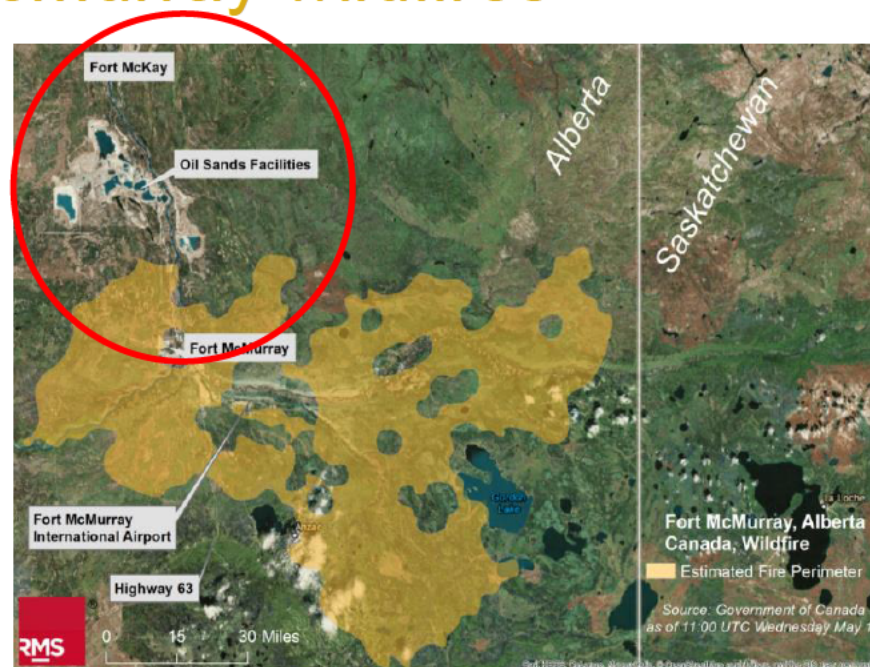

# Counterfactual Analysis

## Case Study: 2016 Fort McMurray wildfires

**Curiosity:** a possible near-miss?

Could prevailing winds have allowed the wildfire to engulf high value oil sands facilities north of Fort McMurray?

Little or no business interruption (BI) losses from oil sands projects were included in the estimates (see previous slide). However, BI can be a significant loss driver as illustrated by Alberta Sands (2011) and Suncor (2005) losses where finalised BI claims totalled US\$250m and \$830m respectively (Canadian Underwriter)

### ANATOMY OF A FOREST FIRE

#### FUEL LOADS

Wildfires spread based on the type and quantity of fuel that surrounds them. This can include everything from trees, underbrush and dry grassy fields to homes. The amount of flammable material that surrounds a fire is referred to as the fuel load. Fuel load is measured by the amount of available fuel per unit area, usually tons per acre.

#### Tree crown fuel

Tree crown fires are so intense, they're difficult to control.

#### Surface fuel

The main variable in ignition time is the ratio of the fuel's total surface area to its volume. Since a twig's surface area is not much larger than its volume, it ignites quickly. By comparison, a tree's surface area is much smaller than its volume, so it needs more time to heat up before it ignites.

#### Ladder fuel

Ladder fuel allows the fire to move up toward the tree tops.

#### WEATHER

Weather plays a major role in the birth, growth and death of a wildfire. Drought leads to extremely favourable conditions while rain raises the amount of moisture in fuels, which suppresses potential blazes.

#### Wind

Wind is the most unpredictable factor in a wildfire's behaviour. It supplies additional oxygen, further dries potential fuel, and pushes the fire across the land faster.

#### Heat

Temperature affects the sparking of wildfires. The sticks, trees and underbrush on the ground receive radiant heat from the sun, which heats and dries potential fuels. For this reason, wildfires tend to rage in the afternoon, when temperatures are at their hottest.

#### TOPOGRAPHY

Topography can either aid or hinder wildfire progression. The most important factor in topography as it relates to wildfire is slope. The steeper the slope, the faster the fire travels. Fires travel in the direction of the ambient wind, which usually flows uphill. Additionally, the fire can preheat the fuel further up the hill because the smoke and heat are rising in that direction. Conversely, once the fire has reached the top of a hill, it must struggle to come back down because it is not able to preheat the downhill fuel as well as the uphill.

# 2016 Fort McMurray wildfires

## Factors of influence

System  
characteristics

Hazard  
behaviour

### 1. Frequency (ignition):

- an ignition source (human / natural)
- High temperatures,
- Low humidity / no precipitation

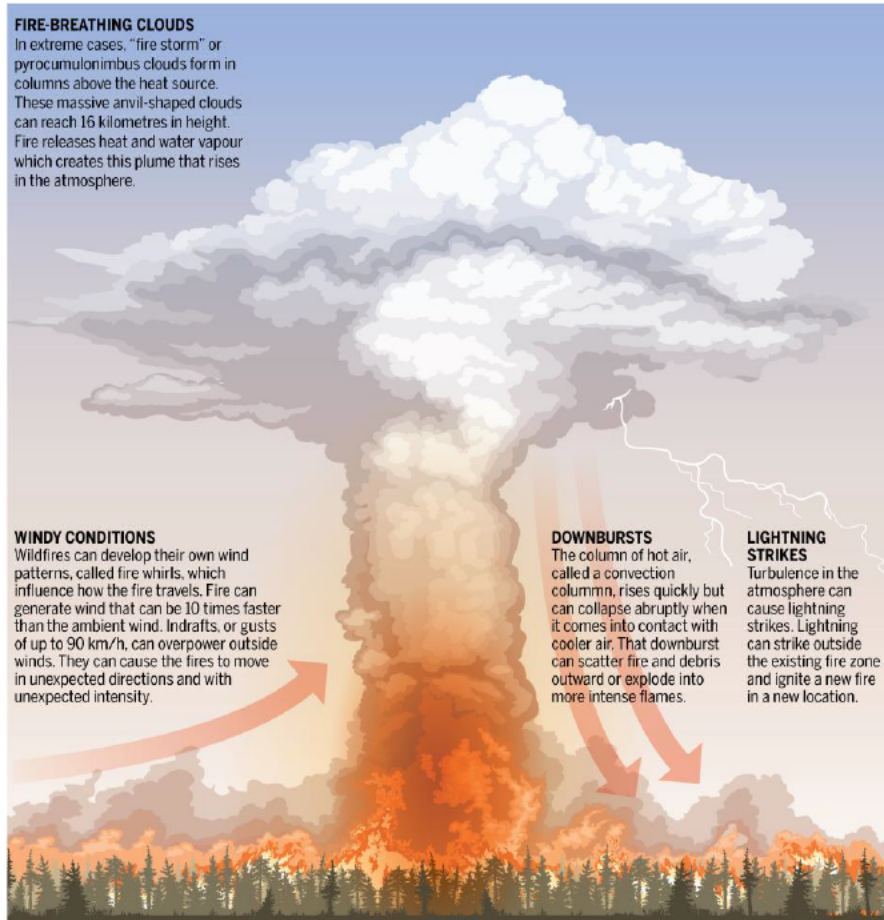

### 2. Severity:

- availability of dry vegetation,
- supportive local topography and
- gusty wind conditions

# 2016 Fort McMurray wildfires

## Range of (adverse) scenarios considered

Scenario  
identification

1. Higher loss to Fort McMurray town
  - 90% of FMM remained intact
  - In contrast, third of 2011 Slave Lake destroyed
2. Increase wildfire duration
  - Slave lake wildfire out of control for 2 days
  - Fort McMurray = +38 days
  - Accelerated loss beyond 30 – 60 day deductibles for industrial risks
3. Damage to Oil Sands facilities
  - High concentration of assets
  - Spared by change in winds from prevailing southerly to westerly
  - What if strong southerly winds persisted?

Institute  
and Faculty  
of Actuaries

# 2016 Fort McMurray wildfires

## Financial Liability Considerations

Severity  
Computation

Damage rates needs to consider:

- Contract attachment and exhaustion points and overall TIV
- Underlying deductibles on industrial risks: 30-120 day time-based deductibles
- Occupancy type and its relationship to assumed production downtime
- Range of reasonable damage rates rather than a single point estimate

Institute  
and Faculty  
of Actuaries

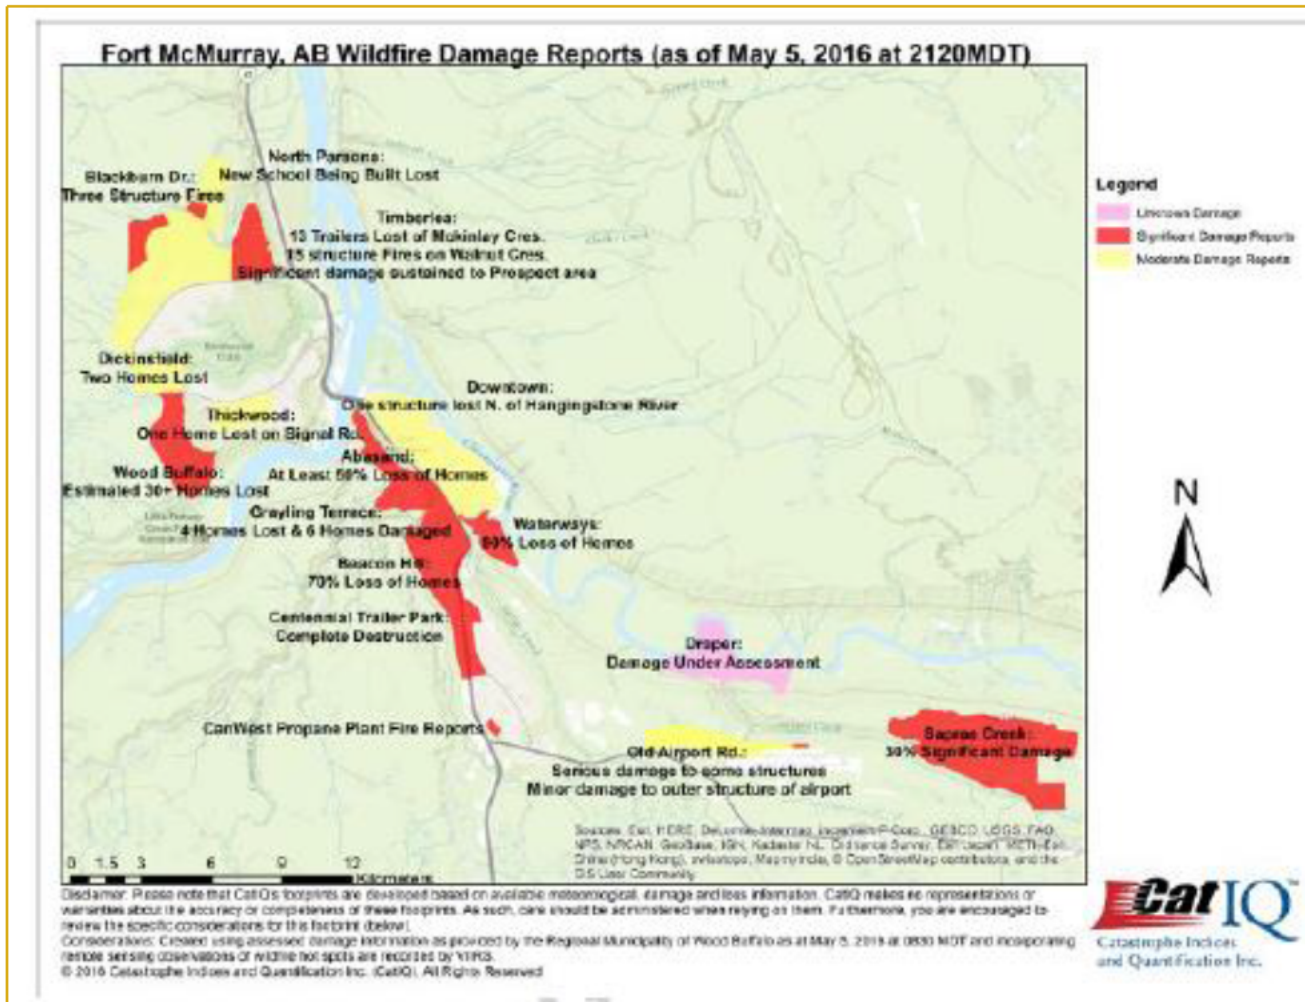

# 2016 Fort McMurray wildfires

## 1. Damage to FMM Town

### Severity Computation

#### Perturbations:

- 10% base
- 25%
- 50%
- 75%

Institute  
and Faculty  
of Actuaries

# 2016 Fort McMurray wildfires

## 2. Wildfire Duration

### Frequency and Severity Computation

- **Frequency:** Estimate persistence of the “30-30-30” rule
- **Hazard extent:** hourly wind direction data from local weather stations to estimate as-if fire footprint
- **Severity:**
  - Ensure availability of dry vegetation for wildfire spread
  - Consider large firebreaks, though not unreasonable to assume limited effectiveness of fire suppression efforts while extreme hazardous conditions persist

# 2016 Fort McMurray wildfires

## 3. Damage to oil sands facilities

Frequency and  
Severity  
Computation

- **Frequency:**
  - hourly wind direction data from local weather stations to estimate likelihood of wildfire spread to oil sands facilities around Fort McKay
  - As at May 6<sup>th</sup> one in eight chance of fires spreading north
- **Hazard extent:**
  - hourly wind direction data from local weather stations to estimate as-if fire footprint
  - Average speed of fire spread = 40m / min (CatIQ) => southerly prevailing winds could have fanned wildfires toward oil sand facilities within one or two days
  - Possible accelerated spread due to pyrocumulonimbus clouds ignitions
- **Severity:**
  - Ensure availability of dry vegetation for wildfire spread
  - Consider large firebreaks, though not unreasonable to assume limited effectiveness of fire suppression efforts while extreme hazardous conditions persist

Institute  
and Faculty  
of Actuaries

## Proximity to Extreme Loss

Communication

Actual loss ranked  
against range of  
scenarios computed

Percentiles or more  
qualitative:  
conservative, best  
estimate, optimistic

Institute  
and Faculty  
of Actuaries

Benefits and limitations

Applications in decision-making

Institute  
and Faculty  
of Actuaries

# Counterfactual Analysis

## Benefits and Limitations

- Compels us to explore the characteristics of a system and the mechanism for producing loss, thus revealing (potentially hidden) lessons from the past:
- Can help make sense of modelled numbers, but also reveal proximity to extreme loss for poorly modelled region-perils
- Catastrophe Risk: Tsunami, liquefaction, earthquake aftershocks and contingent business interruption
- Man-Made catastrophes: Cyber, Terrorism
- Mitigates the prospect of an unpleasant surprise as it reduces outcome bias\*
- Complementary rather than stand-alone as this is not a *push of the button* type scenario, but certainly not labour intensive

Institute  
and Faculty  
of Actuaries

# Counterfactual Analysis

## Application in decision-making

- Improve risk selection in underwriting / pricing
- Refine the reinsurance / retrocession purchase decision
- Improve transparency in exposure management (setting and monitoring capacity)
- Develop Board understanding of proximity to extreme loss

# Counterfactual Analysis

## Goals

1. Understand counterfactual analysis as a validation tool
2. Understand how to apply the approach as illustrated in the context of the 2016 Fort McMurray wildfires
3. Understand the benefits of this approach
