# THE RECENT TREND OF MORTALITY IN GREAT BRITAIN 

By W. S. HOCKING, O.B.E., F.I.A.<br>Of the Government Actuary's Department

FOR the last twenty years or so a series of tables has appeared in the fournal showing the death-rates in age-groups of the general population of England and Wales in successive years and the ratios that those rates bore to the corresponding rates for the years 1930-32, which was the period on which the latest series of English Life Tables was based. This standard period has now become rather remote, and the taking of a Census in the year 1951 and the preparation of new National Life Tables based on that enumeration together with the deaths in adjacent years affords a convenient opportunity to change the standard period to the years 1950-52. At the same time, it is thought that the experience of the whole of Great Britain, rather than that of England and Wales alone, would be of value to British actuaries, though, because of the relative sizes of the two populations, the inclusion of Scottish mortality with that of England and Wales does not, in general, make the trend of mortality for Great Britain differ appreciably from that of England and Wales.

The rates shown in Table a are central death-rates for age-groups, viz. the ratios obtained by dividing the deaths recorded in the year in the specified age-ranges by the estimated population in the age-range at the middle of the year, as estimated by the Registrars General of England and Wales and of Scotland respectively. The deaths are those recorded as occurring in Great Britain and the population used is the 'home' population, i.e. the total population, including British seamen on foreign-going ships and the armed forces in the country, but excluding British forces abroad. For the years 1946-49, however, both deaths and populations were limited to civilians. The relatively high mortality rates of men in the age-groups 15-19 and 20-24 last birthday, particularly in the years $1946-49$, is to be attributed to the exclusion from the experience of part, or the whole, of the armed forces at those ages, with the result that the remaining population, including as it does all those unfit for military service, is somewhat under-average in health. This feature has, however, only a very minor effect on the broader age-group 15-44 last birthday, and its effect on the trend from year to year is negligible, with the possible exception of the year in which the change of basis was made.

The populations used for the years 1950 onwards are revised estimates of the population in the middle of those years made when the age distributions shown by the full tabulation from the 1951 Census became available. In this respect, therefore, the data used differ somewhat from those employed for England and Wales for the years 1950-53 in the tables given in recent issues of $\mathcal{Y}$.I.A. The estimated populations for the years 1946-49 have not been revised by the Registrars General, but the errors revealed by the 1951 Census enumeration were not significant except for the age-group 85 and over, where it was found that the estimated population was $9 \%$ too large for men and $2 \frac{3}{4} \%$ for women. These errors have been assumed to have accumulated over the twenty years since the 1931 Census, and proportionate reductions have
accordingly been made to the estimated populations for that age-group made by the Registrars General for the years 1946-49. For other age-groups the previous estimates have been retained.

Table 1. Death-rates for age-groups in Great Britain in the years 1930-32 and in 1946-54

| Age-group | Year |  |  |  |  |  |  |  |  |  |

- Standardized on mosi Census age distribution

The death-rates up to age 65 have been shown to five places of decimals, but because of the fall in the size of the population over that age (which is estimated by the Registrars General only to the nearest thousand) and the rapid increase in the death-rate itself, the reliability of the final places of decimals diminishes progressively. For ages $65-79$, therefore, only four places of decimals have been tabulated, and at ages 80 and over for men and 85 and over for women the number of decimal places has been limited to three.

Table 2. Ratios of death-rates for age-groups in Great Britain in the years $1930-32$ and in 1946-54 to the rates for 1950-52

| Age-group | Year |  |  |  |  |  |  |  |  |  |

* Standardized on 1951 Census age distribution.

Table 2 shows the ratios of the central death-rates in Table I to the average rates for the three years 1950, 1951 and 1952, taken as the standard.

In order that the trend of mortality rates may be conveniently studied, the group death-rates and the ratios to the 1950-52 standard are set out in Tables

3 and 4 respectively, and the ratios to the 1950-52 standard are shown in graphical form on pp. 142-3. In these tables and graphs the age-groups have been reduced to six, viz. under age 1 (infants), $1-4$ (young children), 5-14 (children of school age), 15-44 (younger adults), 45-64 (older adults) and 65 and over (elderly). Further, so as to eliminate the effect of the considerable changes in the age distribution of the population that are taking place, the group death-rates and ratios have been standardized on the age distribution of Great Britain at the 195r Census.

As a link with the earlier series of tables, showing the trend of mortality in England and Wales since $1930-32$, figures for Great Britain for the average of those three years have been included in Tables $\mathrm{x}-4$.

Some salient features of the tables are as follows:
(i) The fall in the mortality rates of children during the last twenty years or so has been startling, the group death-rates for 1954 being from one-third to one-eighth of those of 1930-32, and less than one-half of the corresponding rates eight years earlier. The fall shows no sign of ceasing, the 1954 rates being from $15 \%$ to $30 \%$ below the $1950-52$ standard. The death-rates are, however, now so low that a relatively small absolute change is magnified when it is shown as a percentage variation. Thus, at ages $5-14$ the death-rate for girls is now only one-thirtieth of $1 \%$, and that of boys is not much higher.
(ii) At the younger adult ages the reduction in mortality is also spectacular, the experience during 1954 being little more than one-third of that during 1930-32 and not much over one-half of the mortality in 1946. The fall in mortality rates among young women has been somewhat more rapid than that among men. There has been some slackening in the rate of improvement during the last two years, but the rates of mortality at these ages are now so low (about $\frac{1}{6} \%$ for men and $\frac{1}{8} \%$ for women for the whole group $15-44$ last birthday) that the field for further improvement is limited.

Table 4. Ratios of standardized death-rates for age-groups in Great Britain to the rates for 1950-52 (standardized on 1951 Census age distribution)

| Year | Age-group |  |  |  |  |  | All ages |

(iii) In the twenty-year age group 45-64 the mortality rates of men have fallen since $1930-32$ by about $15 \%$ and those of women by about $35 \%$; since 1946 the fall has been only $5 \%$ for men and $15 \%$ for women. Indeed, for ages 55-64 in the case of men the improvement over the last eight years has been only marginal, made up of a slight worsening during the first half, and a slightly greater improvement in the second half.
(iv) The elderly show a $10 \%$ improvement since 1930-32 in the case of men and one of about $22 \%$ in the case of women. Since $1946-47$ there has been a slight deterioration in the case of men but an improvement of some $7 \%$ for women. At these advanced ages the experience of both sexes has been a slight worsening in the late nineteen-forties, followed by a fall in mortality since $1950-52$ of some $5 \%$ for men and some $10 \%$ for women. This
