### Cash Flow Matching - Reminder

03 October 2013

2

## Think of a Technical Discount Rate (for example, 4.2%)

03 October 2013

3

## Analysing Cash Flows: Two Methods

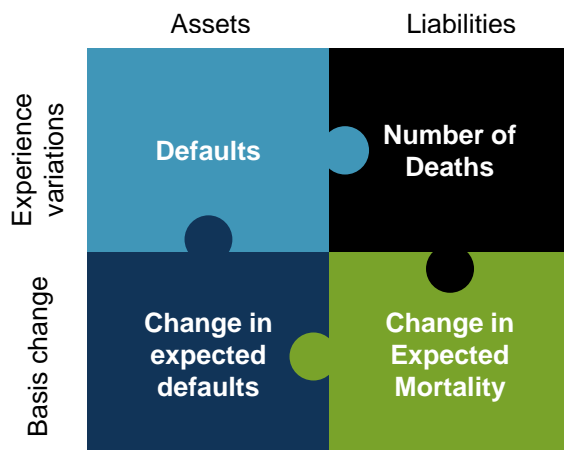

- Method #1
  - We could try to match expected cash flows in buckets
  - But this suffers from arbitrary bucket boundaries
- Method #2
  - Choose a technical rate
  - Calculate PV of future flows at each future date
  - Minimise difference, for example by least sum of squares
- These calculations are cash flow based
  - No reference to market prices or yields

03 October 2013

4

## What if the cash flows change?

- With a one-year risk horizon, we worry about:

03 October 2013

5

## What about market value? Two extremes

### Traditional View

- Difficult to assess if assets are illiquid, trading affects the price, trades are infrequent or not public
- Impossible to assess for liabilities because no market in actuarial decrements
- Only matters if you're buying or selling, while the whole point of cash flow matching is to avoid this.

### Market Consistent View

- Must put a market value for all cash flows, marking to model if no quoted price.
- Changes in market prices imply changes in cash flow expectations
- Balance sheet is more volatile in the market view than the traditional view, although matching alleviates this

03 October 2013

6

## As it turns out ...

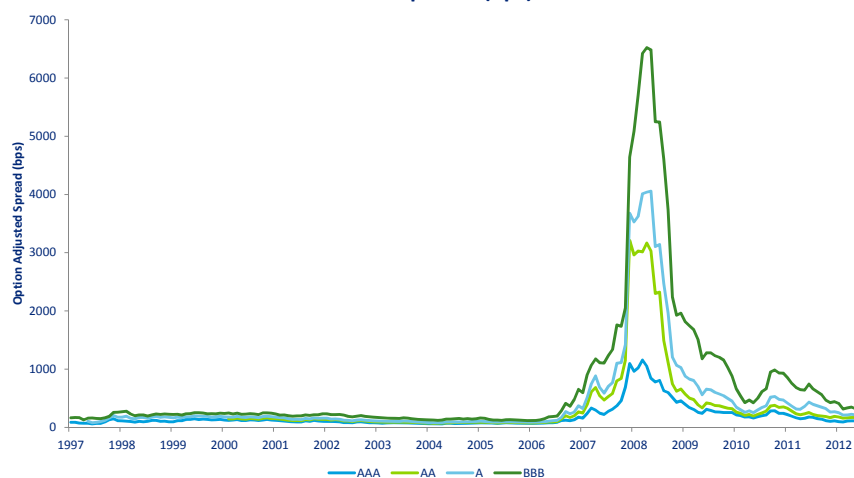

- The market price of the least-squares matching portfolio
- Is the same as the PV liabilities
  - Discounted using the Smith-Wilson formula
  - As used for interpolation / extrapolation for Solvency II
  - With the UFR equal to the technical rate
- It should all hang together so nicely!
- Except that we often calibrate our reference curves to different assets from those held (mostly swaps for S2)
- Therefore the spread between assets held and reference curves creates challenges for ALM

03 October 2013

7

## 2008: Spreads Suddenly Interesting

CMBS Spreads (bps)

03 October 2013

8

## Regulatory Approaches

Solvency I	Solvency II
<b>Liability Discount Rate</b> 97.5% risk adjusted yield	<b>Liability Discount Rate</b> Risk-free (based on swaps) + "matching premium"
	<b>Matching Premium Criteria</b> <ul style="list-style-type: none"> <li>• Must not have borrower options</li> <li>• Rated (BBB or higher)</li> <li>• Must be ring-fenced:               <ul style="list-style-type: none"> <li>• Cannot be actively traded</li> <li>• Diversification with other business not recognised</li> </ul> </li> </ul>
	<b>Globally Significant Insurers</b> Liquidity risk is a key consideration for globally significant insurers driving requirements to prepare risk and recovery planning material.

03 October 2013

9

## Illustrative Comparison of Asset Classes

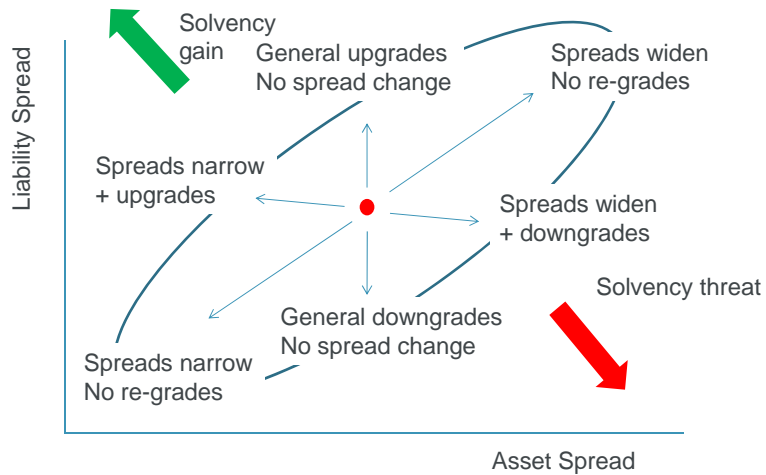

The matching premium compromise is that not all the spread is taken to imply lower expected cash flows.

03 October 2013

10

## Aspects of Asset-Liability Matching if Liability Spread Restricted by Grade

03 October 2013

11

## Spreads are made of Many Elements

### Bond Gross Redemption Yield

- less expected default losses
- less illiquidity losses on forced sale
- less management expenses

### Expected Bond Return

- less cost of default risk capital
- less cost of liquidity capital
- less cost of expense capital
- less unexplained residual

### Liquid risk-free rate

Yield (%)

03 October 2013

12

## Do Not Ignore Illiquidity Cost

### Policy drivers

- Catastrophe insurance payout requires liquidity
- Loss of confidence/adverse publicity triggers surrenders
- No MVA dates cause concentration in withdrawals
- Embedded options moneyness cause concentration in withdrawals
- New product launches trigger surrenders/churn
- Optional additional premiums reduce unexpectedly

### Market drivers

- Delta and other guarantee hedging requires triggers portfolio rebalancing
- Hedge rollover requires liquidity
- Limits on group fungibility trigger the need to move assets
- Derivative delivery requires liquidity
- Collateral posting on derivatives requires liquidity

### Credit drivers

- Downgrades effect on
  - Investment risk appetite
  - Collateral quality
  - Tracking an index
- Accelerated settlement / collateral liquidation through counterparty failures

### Financing drivers

- Debt coupons / principal payments require liquidity
- Merger / acquisition finance requires liquidity
- Collateral payments on securitisation require liquidity

13

## Elements of Reference Curve under S2

03 October 2013

14

## Extrapolation: LLP and UFR Convergence

03 October 2013

15

## ALM Impact of LLP and UFR

- Extrapolation is necessary when liabilities are longer than available assets
- However, in the euro zone for Solvency II there is a lot of pressure to start extrapolation early (for example, from Last Liquid Point = 20 years) even where longer asset quotes are available.
- This currently reduces stated euro liabilities (because the ultimate forward rate of 4.2% is higher than market yields)
- Reduces balance sheet volatility if liabilities are longer than assets, but exacerbates volatility if you match with long assets
- Compared to S2, IFRS is less forgiving of ignoring market prices

03 October 2013

16

## Benchmarking to a “Risk Free” curve

There is no default-free asset. The best we can do is use spreads to convert from one degree of credit risk to another

03 October 2013

17

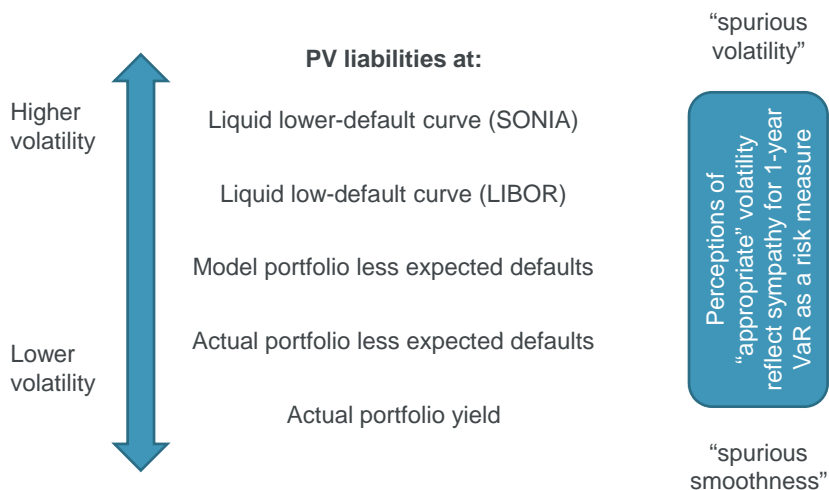

## Credit Risk Adjustment Impact

03 October 2013

18

## Impacts of Discount Choices on 1-Year Value-at-Risk for CF Match

03 October 2013

19

## Conclusions

- In our regulatory environment, there is an inevitable focus on one-year VaR
- You do not have to manage your business this way unless you are especially capital constrained
- Longer term metrics are more congenial to management of long term liabilities
- But it's a challenge to communicate this to stakeholders who are naturally drawn to 1-year RORAC measures
- Some firms have an appetite for longer term liquidity risk and others do not. The key is keeping investors on board.
