## 1. Introduction

In 2004 the UK Asbestos Working Party (the Working Party) produced a paper entitled "UK Asbestos - The Definitive Guide" (the 2004 paper). The paper contained background information and history in respect of asbestos use in the UK, a summary of regulations and legal principles, an Insurance Market survey and estimates of the potential cost to the UK Insurance Market of UK asbestos-related claims. The UK Insurance Market estimates relied on the population mesothelioma deaths projected by the Health and Safety Executive (HSE) as set out in their 2003 paper "Mesothelioma Mortality in Great Britain: Estimating the Future Burden" (HSE 2003). The HSE projections were subsequently published in detail in the paper "The expected burden of mesothelioma mortality in Great Britain from 2002 to 2050" (HSE 2005).

By 2007, evidence was emerging that the correspondence observed in the 2004 paper between the number of UK mesothelioma deaths and insurance claims was breaking down. The Working Party reformed in 2007 to investigate this and to report on developments in general since the release of the 2004 paper.

The Working Party reported in GIRO workshop presentations in 2007 and 2008 and produced a paper "UK Asbestos Working Party Update 2008" (the 2008 paper) outlining the trends, key issues and the important things to consider when estimating UK asbestos-related claims liabilities. At this time the HSE was commissioning its specialist modelling arm, the Health and Safety Laboratory (HSL), to update the HSE 2003 projections. Given that the original HSE study had been a key component in the original Working Party work, it would have given a false impression of certainty to update the Working Party estimates before the HSL update became available. Because of this, the 2008 paper did not contain an update of the 2004 estimates of the UK Insurance Market cost.

In August 2009, the HSL published its update, outlined in the paper "RR728 Projecting Mesothelioma Mortality in Great Britain" (HSL 2009). Separately, at a conference in Melbourne in April 2008, Professor Julian Peto, Cancer Research UK Chair of Epidemiology at the London School of Hygiene \& Tropical Medicine, had presented projections of worldwide mesothelioma deaths "Asbestos-related cancer deaths - the past, present and future". These projections were based on an age, birth cohort model and included the UK. By 2009 two alternative approaches to the projection of future mesothelioma deaths were therefore in the public domain.

In order to compare these models and understand their implications for UK Insurance Market cost, the Working Party has been in dialogue with the HSE and Prof. Peto over the course of 2009. This paper sets out the Working Party's findings: a detailed discussion of the models used by the HSL and Prof Peto, a comparison with a simpler, latency-driven approach and a reprojection of the potential cost of asbestos-related claims to the UK Insurance Market.

The analysis of mesothelioma claim costs has been aided considerably by the collection, coordinated by the ABI, of financial data for an anonymous random sample of settled mesothelioma claims from a number of insurers.

This paper presents the results of a survey of aggregated asbestos-related claims numbers and costs for a large proportion (estimated to be around 80\%) of the UK Insurance Market. As well as giving an insight into trends in claim development, this survey has facilitated the estimation of future costs for non-mesothelioma claims.

This paper addresses the "things to consider" that were highlighted in the 2008 paper. The Working Party recommends that the 2008 paper, which discusses the main reasons for the divergence between the actual and expected experience over the last few years, be read alongside this paper. For ease of reference, the 2004 estimates, as summarised in the 2008 paper, are reproduced in Appendix A.

The Working Party defines the UK Insurance Market as all direct (including London Market) insurers, Lloyd's syndicates and captive insurance regardless of whether the entities are now currently solvent or insolvent. It does not include central Government, nor local authorities except to the extent they are covered by commercial insurance.

The estimates in this paper cover UK asbestos-related claims covered by employers' liability insurance policies written by the UK Insurance Market. They do not include asbestos-related claims that may fall to public liability insurance policies, or non-UK asbestos-related insurance claims.

The estimates in this paper do not include any amounts in relation to pleural plaques. As clarified in the House of Lords ruling on 17 October 2007, asymptomatic pleural plaques are not compensable in England and Wales. Legislation has been passed in Scotland that means asymptomatic pleural plaques are compensable there, but this is currently undergoing a judicial review process. Northern Ireland has announced its intention to make asymptomatic pleural plaques compensable but no bill has yet been put forward.

There is a large amount of uncertainty in respect of the future cost of UK asbestos-related claims to the UK Insurance. The 2004 paper quoted a central ("medium/medium") estimate of the cost together with low and high estimates. However, we believe, particularly in relation to the number of mesothelioma sufferers who make insurance claims, that there is insufficient evidence on which to base a single best estimate of the future cost. Instead, this paper presents scenarios that provide alternative approaches to the modelling of, amongst other things, future deaths, the proportion of sufferers who claim and future claim inflation. Using this information, the paper reports on a range of reasonable best estimates, given current knowledge, for each asbestos-related disease.

It is possible that the actual cost of UK asbestos-related claims turns out to be outside the range of the estimates contained in this paper. For example, changes in the law or in medical technology could have profound implications. It remains vital to monitor closely actual experience over time against prediction: suggestions on the main areas to monitor are discussed later.

The ubiquity of asbestos and the danger it poses to human health have had, and will continue to have, profound consequences. It is estimated that mesothelioma has been responsible for over two hundred thousand deaths to date worldwide; many more are likely to die in the future. This paper deals with one aspect: the financial impact of UK asbestos-related claims. Whilst this paper focuses on the financial cost of claims it is by no means intended to treat the real human issues lightly. The wider social and human aspects are rightly examined elsewhere.

## 2. Executive Summary

The Working Party has estimated that the undiscounted cost of UK mesothelioma-related claims to the UK Insurance Market for the period 2009 to 2050 could be around £10bn. Of this figure, over $£ 8 b$ b relates to the period 2009 to 2040 , which is approximately double the estimate of $£ 4 b n$ for the same period that was presented in the 2004 paper. The estimate made in 2004 did not include periods after 2040.

The updated estimate is highly uncertain, and it is possible that the actual outcome could be appreciably more or less than this amount. For example, alternative scenarios give a cost of around $£ 5 b n$ or over $£ 20$ bn for the period 2009 to 2050.

Whilst there have been some changes to the model adopted as described elsewhere in this paper, the increase in the Insurance Market estimate has been driven by the increase in the observed number of mesothelioma insurance claims since 2004. This experience has led the Working Party to revisit the assumptions and methodology that were adopted in 2004. It is not possible to draw any conclusions from the change in the Insurance Market estimates regarding the current level of insurance company reserves as insurers will already have factored the observed experience into their reserve estimates to some degree.

Mesothelioma-related claims give rise to the vast proportion (over 90\%) of the estimated total UK asbestos-related claims cost for the UK insurance industry. Including the potential cost of asbestos-related lung-cancer, pleural thickening and asbestosis claims, the total UK Insurance Market future cost of UK asbestos-related claims could be around $£ 11$ bn. This compares to the estimate of $£ 4.7$ bn presented in the 2004 paper. The estimate made in 2004 did not include periods after 2040.

The Insurance Market estimates do not include any amounts in relation to pleural plaques. As clarified in the House of Lords ruling on 17 October 2007, asymptomatic pleural plaques are not compensable in England, Wales and Northern Ireland. Legislation has been passed in Scotland that means pleural plaques are compensable in Scotland, but this is currently undergoing a judicial review process. This is discussed further in Section 8.

The total change in the estimated cost of asbestos-related claims to the UK Insurance Market compared to that estimated in 2004 is explained in the following table and discussed in more detail below.

Table 1: Summary of the Changes in the UK Insurance Market Estimate

|  | Impact on UK <br> Insurance Market <br> Cost (£bn) |
| :--- | :---: |
| 2004 Estimate (2009 to 2040) | 4.7 |
| Change due to Projection of Population Mesothelioma Deaths | 0.6 |
| Change due to Proportion of Deaths that Result in a Claim | 3.7 |
| Change due to Average Cost | 0.7 |
| Change due to Inflation | $(0.6)$ |
| Change due to Extension of Projection Period to 2050 | 1.7 |
| Change due to Non-Mesothelioma Claim Types | 0.5 |
| 2009 Estimate (2009 to 2050) | 11.3 |

## Recent Experience

Since the Working Party paper in 2004, there has been an increase in experience in relation to mesothelioma claims. Asbestos-related lung cancer claims have also been higher than previously expected. Asbestosis claims have been broadly in line with expectations, whilst pleural thickening and pleural plaques claims have been less than expected following legal developments affecting asymptomatic pleural plaques. The main impact on the UK Insurance Market from mesothelioma claims is illustrated by the graph below:

Figure 1: Mesothelioma Insurance Claims Experience 1968-2008

This graph highlights how the claims experience has deviated from the previous consistency with the actual number of mesothelioma deaths. The number of insurance claims has been increasing faster than the level of population mesothelioma deaths for the last few years.

This has given rise to an increase in the actual incurred costs of mesothelioma claims for the period 2004-2008 compared to that expected within the projection made in 2004. The 2004 paper gave a range of $£ 396 \mathrm{~m}-£ 437 \mathrm{~m}$, compared to the current incurred costs of $£ 924 \mathrm{~m}$ for the period 2004-2008. This observed experience is the main reason why the future projection (post 2009) has been reassessed.

## Population Mesothelioma Deaths

## Revised mesothelioma population death projections have an impact of increasing the Insurance Market cost for the period between 2009 and 2040 by around £0.6bn.

The level of population mesothelioma deaths has not been too different to that expected during the period 2004 to 2008 and hence this is not the main reason for the deviation in experience over this period. However, there is a large level of uncertainty surrounding the future number of people in Great Britain that will be diagnosed with mesothelioma. The HSE ${ }^{1}$, Prof. Peto ${ }^{2}$, and the $\mathrm{HSL}^{3}$, have made projections of the number of mesothelioma deaths expected in Great Britain in the future. Both the HSE and Prof. Peto agree that the models used are only reliable in the short term e.g. over the next 10 years. Beyond this period there is considerable uncertainty.

We have considered a number of different model structures - a simple "latency" model, a birth cohort model, and the HSE / HSL model structure - to project the future level of population mesothelioma deaths. These are discussed in detail in Section 4 of the paper. Each of the models used are shown to fit the past data well, yet they produce materially different future projections. This is the main reason why there is a large range around the estimate of the future cost of mesothelioma-related claims.

We consider that the model structure used by the HSE / HSL appears to be the most appropriate model structure to use to project future mesothelioma deaths. The Working Party has, however, used different assumptions to those used by the HSL 2009 to estimate the future number of mesothelioma deaths within its estimate of the total cost to the UK Insurance Market.

Specifically, we have adjusted the probability of developing mesothelioma at older ages, as this gives a better fit to the past data. The future mesothelioma incidence rate in the population by year of birth cohort is difficult to model. The future mesothelioma incidence rates in the population may turn out to be very different to that currently assumed.

Another departure from the HSL 2009 assumptions is that we have assumed a different exposure profile post 1978. The exposure profile assumed post 1978 does not directly impact the fit of the model to the past experience, but it does impact the projected level of future mesothelioma deaths. We believe that the exposure post 1978 should fall more in line with asbestos imports.

We have adopted other assumption changes compared to the HSL 2009 projections and these are discussed in more detail in Section 4.5 of the paper.

The different models give widely different results. Even within one model structure, slightly different assumptions can be used that continue to give a good fit to the past data but lead to materially different future projections. This gives rise to considerable uncertainty in relation to the future number of mesothelioma deaths both from the uncertainty in the correct model structure to use (model error) and the correct assumptions to use (parameter error). A number of alternative scenarios have been considered in this paper to illustrate the sensitivity of the results to this uncertainty. It is these scenarios that give rise to the wide range of results.

[^0]
## Proportion of Mesothelioma Deaths that Result in a Compensation Claim

## Revised assumptions for the proportion of mesothelioma sufferers that will make a claim for compensation from their former employer have an impact of increasing the Insurance Market cost for the period between 2009 and 2040 by around £3.7bn.

In 2004 there seemed to be a close correspondence between the number of deaths due to mesothelioma and the number of insurance claims being notified. It was observed that around one third of deaths resulted in an insurance claim and this relationship was assumed to continue. The 2004 paper made the observation: "In our projections...we have assumed there is no change in the proportion of people claiming. If this were to increase then the projections could be understated."

Since 2004 it has been observed that the proportion of mesothelioma deaths that result in an insurance claim has almost doubled. This is the main reason why the Insurance Market claims experience has been worse than expected in the period 2004 to 2008, and why the Insurance Market estimates for the period post 2008 have increased compared with those outlined in 2004.

The Working Party has investigated, by communicating with the various parties involved in the mesothelioma claim process, what the key drivers are behind this increase. The Working Party found that there is no single explanation but all of the following have had an influence:

- Publicity. With the various legal cases that have taken place over the last few years, compensation for mesothelioma has often been in the news headlines, and hence public awareness of the availability of compensation is likely to have increased.
- The use of the internet has increased over the last few years and hence access to specialist information and the ability to bring people with a common interest together, no matter the physical distance apart, has improved. There is a wealth of information available on the web to help patients and their carers find out more about asbestosrelated conditions, treatment, symptom management and support, both personal and financial.
- The NHS National Mesothelioma Framework has improved support for mesothelioma sufferers. There has been an improvement in the pre-death diagnosis rate in a number of specialist centres. It is understood that the claim success rate increases when the claim is made prior to death due to the ability to obtain a witness statement from the sufferer. An increase in pre-death diagnoses has increased the likelihood of successful claims against former employers and / or their insurers.
- Anecdotally, it was suggested that as awareness has improved it is possible that there has been an increase in the number of claims made retrospectively (e.g. by relatives after the sufferer has died) even where the death certificate did not state the cause of death to be mesothelioma.

These factors are discussed more fully in the 2008 Working Party update paper. This paper develops future scenarios for the proportion of deaths that result in compensation claim being made. Possible alternative scenarios have been adopted and are fully discussed in Section 5 of this paper. It is extremely difficult to get behind the key drivers as outlined above, and to estimate the influence, if any, these factors will have in the future. This increases the uncertainty surrounding the future projected cost. The following graph shows the Working Party's population mesothelioma deaths projection and three of the five projection scenarios (CD Scenarios) considered for the number of claimants against either the Insurance Market or the Government.

Figure 2: Potential Future Population Mesothelioma Deaths and Claimants

## Average Cost of a Mesothelioma Claim

Revised assumptions for the average cost of compensation provided to mesothelioma sufferers have an impact of increasing the Insurance Market cost for the period between 2009 and 2040 by around £0.7bn.

A sample of mesothelioma claims has been analysed and a model of the average claim size by age and year of settlement developed, as set out in Section 6 of this paper. The sample enabled a more robust and detailed analysis to be carried out than was carried out in 2004. This data is based on actual settlement values and therefore provides a better indicator than the summary market data, which in recent years is based on reserves. This analysis has shown that the estimate made of the average cost of a mesothelioma claim paid to a claimant in 2004 was lower than the actual experience. The average claimant cost experienced in 2008 is greater than that assumed in 2004 and this has increased the estimated total Insurance Market cost.

## Future Inflation of a Mesothelioma Claim

## Revised assumptions for the expected future inflation affecting the cost of compensation provided to mesothelioma sufferers have an impact of decreasing the Insurance Market cost for the period between 2009 and 2040 by around £0.6bn.

The analysis into the claimant costs demonstrated that a greater proportion of the claim is influenced by the age of the claimant than was assumed in the 2004 model. This has resulted in a larger off-set to inflation than was previously assumed to be the case. Further, it is anticipated that the future claims inflation is likely to be lower than that assumed in 2004. Economic factors and a more detailed analysis of the individual heads of claim both lead to this conclusion. As mesothelioma claims are expected to occur over the next 40+ years, the uncertainty in respect of the future inflation level has a large impact on an undiscounted basis. The average cost experience since 2004 is discussed in Section 3 and the revised average cost assumptions are explained in more detail in Section 6 of the paper.

Projection Extended to 2050

## Extending the projection to from 2040 to 2050 has an impact of increasing the Insurance Market cost by around £1.7bn.

The 2004 Insurance Market estimate cut-off the future projection in the year 2040. The cut-off was used as a proxy to allow for the impact of non-occupational exposures and to adjust for the exposure post 2004 used in the model having an influence on the projection. This paper considers the total future cost of asbestos-related claims and we consider it more appropriate to cut-off the projections at 2050. The potential impact of non-occupational exposures has been allowed for explicitly, and the market cost estimated in this paper relates to all asbestos exposure that has occurred or is expected to occur in the future. Claims arising from future exposures do not represent a current liability, but rather a future liability. We would expect insurers to adjust the results appropriately for their current exposure.

## Other Asbestos-Related Claims

Revised projections for asbestos-related lung cancer, asbestosis and pleural thickening claims have an impact of increasing the Insurance Market cost by around $£ 0.5$ bn.

The future cost of these claim types to the UK Insurance Market is estimated to be around $£ 1.2 \mathrm{bn}$. Each of these non-mesothelioma claim types is difficult to project into the future. We have taken a pragmatic approach for these claim types and have made future projections based on a number of alternative scenarios given the past experience. Lung cancer claims are considered to be the most uncertain of these claim types. We have developed a model that relates asbestos-related lung cancer claims to smoking-related lung cancer occurrences. This has helped produce alternative scenarios and hence illustrate the uncertainty surrounding claims of this type. The future projections for these claim types are set out in detail in Section 8 of this paper. The main reason for the increase in the cost of these claims is due to reflecting the greater than previously expected experience for asbestos-related lung cancer claims.

## Future Monitoring and Recommendation

There is a large uncertainty surrounding any estimate made for the total Insurance Market cost of asbestos-related claims. The uncertainty will reduce as the actual experience emerges especially once the peak in claims and deaths is observed, and hence it is critical that the assumptions made to derive the estimates contained in this paper are monitored closely and adjusted as appropriate in the future. Section 10 outlines the main areas that the Working Party propose to monitor in the future.

The Insurance Market estimates outlined in this paper should not be used without a full understanding of all the limitations and assumptions made. The Working Party encourages the actuary responsible for estimating asbestos-related liabilities to form their own view of the assumptions suitable for the liability being estimated. For example, the market estimates in this paper contain an allowance for future exposure to asbestos post 2009 in line with that assumed by the HSE, and this may not be appropriate for establishing claim liabilities. We consider that, in the absence of a more detailed understanding of a portfolio, the UK Insurance Market estimates contained in this paper are suitable for a high level benchmarking approach for a portfolio that has similar overall characteristics to the market.

## 3. Experience since 2004

### 3.1. Summary

The actual claim amounts incurred in the period 2004 to 2008 have been greater than expected for mesothelioma and asbestos-related lung cancer claims, in line with that expected for asbestosis claims, and lower than expected for pleural thickening and pleural plaques claims compared with the medium / medium (medium projected claim numbers and medium claims inflation) forecast set out in the 2004 Working Party paper. The actual versus expected experience based on the market survey data is shown in the following table:

Table 2: Actual Compared to Expected Experience 2004 to 2008

| $£ m$ | Period 2004-2008 |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  | Mesothelioma | Asbestosis | Lung <br> Cancer | Pleural <br>  <br> Pleural Plaques | Total |
| 2004 Projected | 417 | 174 | 21 | 657 | 1,269 |
| Actual as at 2008 | 924 | 174 | 58 | 147 | 1,303 |

Pleural thickening and pleural plaques are different claim types. They are only combined in the above table as they were combined in the 2004 projection, therefore any allocation would be arbitrary.

This Section of the paper reviews the experience in the period 2004-08 by claim type in more detail. Section 3.2 summaries the data collected. Section 3.3 discusses issues related to the data quality and consistency with the data collected in 2004, and Section 3.4 then discusses the observed trends by claim type. The trends are based on the summary data collected from insurance companies and relate to insurance claims rather than individual claimants. The data therefore only covers claimants that make a claim to at least one of the survey participants and each individual claimant may appear more than once in the data collected.

### 3.2. Data Collection

One of the key aims of the Working Party was to collect insurance company claims data to enable an analysis of the trends and features in the data for recent years to be undertaken. Section 5 of the 2008 paper contained this analysis based on data to mid 2007. The data collection was subsequently repeated as at 31 December 2008. The analysis below concentrates on the comparison of the recent experience with the projections made in 2004.

There were two main data sets collected, a summary data set which related to aggregate data (e.g. number of notified asbestosis claims in a given year) and a detailed data set which collected more information for individual mesothelioma claims on a claim-by-claim basis (e.g. collecting year of birth and year of first exposure for each claim). The Working Party obtained advice to ensure that the data collection exercise complies with the Data Protection Act and Competition Law. Copies of the templates for the summary and detailed data collection exercises are included in Appendix B for reference.

We collected data on the following claim types:

- Mesothelioma
- Asbestos-related Lung Cancer
- Asbestosis
- Pleural Thickening
- Pleural Plaques

12 companies participated in the aggregate data collection exercise and 7 companies participated in the detailed data collection exercise. The Working Party is extremely grateful for all the companies' assistance.

All data was collected on an anonymous basis and aggregated via the Actuarial Profession. Some of the Working Party members then produced summaries of the aggregated anonymous data collected at the Institute which were then circulated to all Working Party members. No Working Party member was allowed to take copies of the original data set.

Note that although most of the items requested had enough data for some form of credible analysis, not all of the requested data was complete or available. In particular, there were not enough adequate responses received on the average share of claims met by individual insurers to enable this to be analysed.

The detailed mesothelioma data was provided as at 31 December 2008. The summary data was also typically provided as at 31 December 2008 although some participants produced data sets as at earlier dates.

### 3.3. Consistency with 2004

Before proceeding further, it is worth comparing the latest survey results with the survey results from the 2004 paper for the time periods where they overlap. It is important to note that (particularly for older data) several assumptions are required when grossing-up results to the full Insurance Market level. The two most crucial assumptions required are:

1) What \% of the market is assumed to be captured by the survey data.
2) How to allocate out "unidentified" asbestos-related claims into the constituent claim types (mesothelioma, asbestosis etc.).

On the first point, both this paper and the 2004 paper assumed their survey collected data for $80 \%$ of the Insurance Market. While the 2004 paper made this assumption based on judgement, further analysis during 2008 and 2009 of the Compensation Recovery Unit data (see Section 5.4.3) confirmed that this assumption was indeed reasonable. That said, the participants in the 2004 and 2008 surveys are unlikely to be identical (due to the anonymity of the survey process, we can't be sure on this point) which will produce some differences.

The second point presents more difficulties and a greater degree of approximation. In the 2004 survey, less than half of the companies surveyed were able to provide any kind of history of their claims split by claim type. This meant a significant degree of approximation (using the data where a split was available) was required to estimate the total number of claims by claim type.

Since 2004, the situation has improved significantly. In the data collected, $96 \%$ by number of the claims notified for 2008 were split down by claim type. Therefore, there is a lot more confidence in the split of claims by claim type for the recent years. There are still some significant approximations required for historical data. Only $79 \%$ by number of the claims notified for 2000 and $51 \%$ by number of the claims notified for 1990 were split down by claim type.

Because of these two approximations there are a number of fairly sizeable discrepancies in the two data sets (particularly with regards to average costs), although the high level trends remain very similar. Overall, the Working Party believes that the 2008 survey data is of substantially higher quality due to the improved data collection processes in place, and therefore the projections set out in this paper will be more robust than those in the 2004 paper.

Detailed commentary by claim type is contained within Section 3.4, comparing the actual experience in the period 2004-2008 with the projected experience from the medium/medium 2004 estimates.

### 3.4. Survey Results

Each of the following sections include a chart showing the summary data collected for that claim type. These show claim number statistics and the average cost per claim based on insurance claim notifications in each year, including nil claim notifications. Commentary is also provided on the trend in the average cost of non-nil claims by settlement year, as this can provide added insight in certain cases. Where 2008 year figures have been provided on a part year basis they have been scaled-up pro-rata to a full year.

For the avoidance of doubt, all historical data and projections referred to below have been grossed up to $100 \%$ of the market and unidentified claims have been allocated pro-rata to claim type. They are therefore all a "like for like" comparison. The projections are based on the medium / medium forecast set out in the 2004 Working Party paper.

Two features of the data are worth bearing in mind. Firstly, the data has been split by claim type more accurately in the last five years than in previous periods. This means that the data prior to 2003 may not be as complete and accurate as that for more recent periods. Secondly, the claims notified pre 2006/7 will be largely settled, whereas claims notified post 2006/7 will still be largely outstanding. Hence it is difficult to draw any conclusions in respect to inflation trends using recent incurred data.

### 3.4.1. Mesothelioma

Figure 3: Mesothelioma Experience 1990-2008

The estimated number of insurance industry claims for mesothelioma over the period 19902002 is broadly consistent in both surveys. The differences in the early 1990's demonstrate alternative assumptions around the allocation of unidentified claims to claim types. For the 2004 survey, the stated number of claims in 2003 was highlighted as an "anomaly" and put down to the spike in total claims that year. There was also uncertainty with the estimation approach used to derive the full 2004 year number of notifications at that time.

While there was certainly an element of overestimation in the approach taken (as the revised estimate of mesothelioma claims in 2003 has fallen from c.2,600 to c.2,000) it is clear that 2003 saw the first stage of the noticeable increase in mesothelioma notifications that has been observed in the last five years. Projected total claim numbers for the period 2004-2008 were c. 7,500 compared to actual claims of c.12,500 - an overall difference of more than $65 \%$.

The difference is almost entirely down to the change in the proportion of deaths that result in a compensation claim. As set out in more detail in Section 5 of this paper, this has increased from around $36 \%$ to around $61 \%$ for the UK Insurance Market (excluding Government claims ${ }^{4}$ ) over the period from 2002 to 2008. The assumption that this proportion would remain constant going forward was a critical assumption in the 2004 paper that has not been borne out by events. In respect of the underlying mesothelioma deaths, actual deaths have been very close to those projected in 2004. The HSE model projected deaths in the period 2002-2007 would be 9,959 and actual deaths have been 10,175, a difference of less than 2.5\%.

With respect to average costs, there seems to be a difference between the averages collected in the 2004 survey and the 2008 survey. For the reasons explained in Section 3.3 we believe the data collected in the 2008 survey to be more accurate. In particular, over the last four years there has been a big improvement in the survey participants being able to split out asbestosrelated claims data by claim type. Part of the difference in average claim sizes may also be explained by development on the average costs collected in 2004 although the level of this cannot be determined from the data available.

Average costs have increased at an average rate of around 7\% per annum between 1990 and 2008. However, this figure will be distorted by the uncertainties in the incurred claims in recent years. The change in the average claim amount is also distorted by a change in the number of claims per claimant since 2003 as outlined in more detail below. Average settled costs on nonnil claims on a settlement year basis have decreased slightly in 2007 and 2008 from the level in 2006. Current average settlement costs are around $£ 80 \mathrm{k}$ per insurance claim. Allowing for these distortions the recent inflation rate for mesothelioma claims appears to be around 3\%-4\% per annum, which is slightly lower than that assumed in 2004.

Given that both the numbers of claims and the average costs from the 2004 projection have proved to be underestimated, it is not surprising to find that the actual incurred costs of mesothelioma claims for the period 2004-2008 have also been above expectation. The 2004 paper gave a range of $£ 396 \mathrm{~m}-£ 437 \mathrm{~m}$, compared to the current incurred costs of $£ 924 \mathrm{~m}$ for the same period. Around two-thirds of the difference can be attributed to the under projection of the number of claims and the remaining one-third of the difference can be attributed to the under projection of the average cost per claim. However, it should be noted that the average cost per claimant has not increased as much due to a change in the number of insurance claims per claimant (see below). Hence the impact of the revised average cost per claim on the future projections is not so great (see Section 7).

The apparent difference in average costs has been explored in further detail in an attempt to split out the various components that influence it. The following issues play a factor:

1) The level of compensation paid to claimants;
2) The level of expenses associated with the handling of the claim (legal costs etc);
3) The proportion of claims which settle at nil cost; and
4) The average number of insurers involved for any individual claimant.

The first two amounts can be derived from a ground-up analysis of the cost of a claim (see Section 6). By applying assumptions for 3) and 4) it is possible to derive a theoretical "average cost" per insurance claim. This comparison has been performed for both 2003 notifications (assumed to settle in 2005) and 2006 notifications (assumed to settle in 2008).

The estimate of the claimant costs used in the 2004 paper was inferred by adjusting the average incurred costs of insurers by the assumed number of claims per claimant of 2.5. This was compared to the range given for a $100 \%$ claim in the survey of $£ 50,000$ to $£ 175,000$. A similarly judgemental estimate was made for the legal costs proportion and the proportion of nil claims.

[^1]From the 2008 survey data, it can be seen that the nil claims rate and the legal cost proportions have both remained fairly static (although these figures are still subject to uncertainty). However, the number of claims per claimant has been falling over the period from 2.5 in 2003 to 2.1 in 2008. This is demonstrated from an analysis of the Compensation Recovery Unit (CRU) data as outlined in Section 5.4.3. All other things being equal, a fall in the claims per claimant ratio will lead to an increase in the average cost of claims, over and above any inflation in the 100\% claimant cost.

A final issue relates to costs that will be paid to claimants who are also making an insurance claim but are not picked up by insurers (e.g. payments made by the FSCS on behalf of insolvent insurers or payments made by the Government). This will serve to slightly reduce the reported average cost compared to the average cost per claim model described in Section 6. It is very difficult to quantify this impact, but it is not expected to be significant, as many claims in this category will be paid $100 \%$ by the FSCS / Government. The following tables summarise the assumptions made and compare with the actual experience.

Table 3: Mesothelioma Average Cost Assumptions / Experience

| Notification Year | Assumed <br> Settlement <br> Year | $100 \%$ <br> Claimant <br> Cost (£) | Legal Cost <br> $(\%)$ | Estimated <br> Nil \% | Estimated <br> No. of <br> Claims Per <br> Claimant |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2003 (as per 2004 survey) | N/A | 156,250 | $15.0 \%$ | $20 \%$ | 2.5 |
| 2003 (as per 2009 survey) | 2005 | 160,234 | $17.3 \%$ | $21 \%$ | 2.7 |
| 2006 (as per 2009 survey) | 2008 | 176,657 | $17.7 \%$ | $21 \%$ | 2.2 |
| 2008 (as per 2009 survey) | 2010 | 179,519 | $18.8 \%$ | $21 \%$ | 2.1 |

|  | Implied Average (£) |  | Actual Average (£) |  |
| :---: | :---: | :---: | :---: | :---: |
| Notification Year | incl Nil | excl Nil | Notified incl <br> Nil | Settled excl <br> Nil |
| 2003 (as per 2004 survey) | 50,000 | 62,500 | 50,000 | $\mathrm{~N} / \mathrm{A}$ |
| 2003 (as per 2009 survey) | 46,673 | 59,111 | 65,552 | 74,938 |
| 2006 (as per 2009 survey) | 62,497 | 79,110 | 72,987 | 79,566 |
| 2008 (as per 2009 survey) | 67,882 | 85,927 | 83,698 | $\mathrm{~N} / \mathrm{A}$ |

The figures in the table above have been derived from the market survey data collected and the mesothelioma claims sample referred to in Section 6.

The above data suggest that:

- The inflation rate implied by the average insurance claim over the period 2003 to 2008 is distorted by the fall in the number of claims to claimant (from 2.7 claims per claimant to 2.1 claims per claimant). Therefore it is better to consider the total claimant cost when deriving the underlying claims inflation. The inflation rate is less than 3\% per annum over the period 2003 to 2008, and hence more in line with the inflation assumptions outlined in Section 6.
- Current average costs for the 2006-2008 notification years from the market survey appear reasonable compared to the data underlying our average cost per claim model (see Section 6). Note that more weight should be placed on the settled costs since the actual incurred averages may be slightly overstated as not all nil claims will be settled and consequently reflected in the average.
- The 2004 estimate of the Insurance Market average claimant cost for mesothelioma was low. The 2004 estimate of $100 \%$ claimant costs was around $10 \%$ lower than actual claimant costs at that time.

This analysis is inevitably distorted by the imperfect match between notification year and settlement year information.

The data that has been used within the Insurance Market cost projections for mesothelioma claims has been derived from a sample of claimant claims costs (i.e. compensation at the $100 \%$ level). This is discussed more fully in Section 6, and avoids the problems due to the falling claims per claimant ratio as outlined above.

### 3.4.2. Asbestos-related Lung Cancer

Figure 4: Lung Cancer Experience 1990-2008

In comparing to the 2004 data, the comments regarding asbestos-related lung cancer claims over the period are very similar to those for mesothelioma for claim numbers but not for claim amounts. Overall the historical data is reasonably consistent, but with higher notifications now recorded for the period 2000 to 2003 . This is probably due to improved claim type identification and the anomalies to the allocation of unidentified claim types as discussed in Section 3.3. The experience since 2003 has been notably higher than projected. There has been an upturn in notifications, increasing from around 200 to over 300 per annum since 2004. Levels are still around $10 \%$ of those for mesothelioma however, and average costs compared to mesothelioma are somewhat lower.

Total claim numbers for the period have been c. 1,300 compared to a projection of c.500. The reasons for this are likely to be at least partly attributable to improvements in data quality, and the difficulty in performing projections for this claim type. Asbestos-related lung cancer was highlighted as a significant area of uncertainty in the 2004 paper. Further consideration of the trend in asbestos-related lung cancer notifications is discussed in Section 8.1.

Average costs in both the historical and more recent data appear consistent. The actual incurred cost for 2008 appears anomalously high compared to the recent history, and should be treated with caution due to the limited development for this year. The settlement costs of non-nil claims are somewhat more stable, at around $£ 35,000$.

Overall, the actual incurred costs of asbestos-related lung cancer claims for the period 20042008 has been higher than the 2004 projections. The 2004 paper gave a range of $£ 16 \mathrm{~m}-£ 24 \mathrm{~m}$, compared to the current incurred costs of $£ 58 \mathrm{~m}$ for the same period. Almost all of this difference can be attributed to the under projection of the number of claims.

### 3.4.3. Asbestosis

Figure 5: Asbestosis Experience 1990-2008

Asbestosis experience would appear to be much more consistent with last time's data and resulting projections. The main areas to note are the differences for 1990-1995 which are primarily due to the allocation of unidentified claim types as discussed in Section 3.3, and that the 2004 survey average costs for 2000-2003 would appear to have included a degree of prudence in the early stages of case estimation.

There was discussion in the 2004 Working Party paper that the "peak" for asbestosis-related claims may have already been reached and we should expect claims to reduce in number in the future. Since the peak number of notified asbestosis claims in 2003 the notified claim numbers do appear to be falling.

Total numbers of claims for the period 2004-2008 have been c.9,000 compared to a projection of c.9,500 in 2004, which is reasonably close, particularly compared to the significant differences in the other claim types. Actual average costs for 2008 are currently $£ 25 \mathrm{k}$ compared to a projection of $£ 20 \mathrm{k}$. Average non-nil settlement costs have increased only very gradually, at an average rate of around 3\% per annum since 1990. Current average settlement costs are around $£ 22 \mathrm{k}$ per insurance claim. However, the data does suggest that inflation for asbestosis claims since 2003 may have been much higher than initially projected. This is probably due to the distortion in the average incurred cost for recent notification years - it is expected that the average incurred amounts for the later notification years will reduce as the claims are settled. The average settled claim cost over recent years has been fairly stable (see Section 3.5). It is also possible, though less likely as the dynamics of how the claim is handled are different, that it is distorted by the impact of the reducing claims to claimant ratio as outlined for mesothelioma.

Overall, the actual incurred costs of asbestosis claims for the period 2004-2008 have been broadly in line with the 2004 projection. The 2004 paper gave a range of $£ 157 \mathrm{~m}$ - $£ 197 \mathrm{~m}$, compared to the current incurred costs of $£ 174 \mathrm{~m}$ for the same period.

### 3.4.4. Pleural Plaques

The 2004 paper did not split out the projections between pleural plaques and pleural thickening. Rather than make an arbitrary retrospective apportionment between these claim types within the 2004 estimate, the comparison set out below is for the total of both claim types. This is only to facilitate the comparison of the experience since 2004. The 2009 market survey has enabled these different claim types to be distinguished and hence a projection for pleural thickening claims has now been made - see Section 3.4.5 and 8.3.

Figure 6: Pleural Plaques and Pleural Thickening Experience 1990-2008

It was highlighted in the 2004 paper that experience for this claim type would be very uncertain due to the legal uncertainties of whether or not asymptomatic pleural plaques claims are compensable. Claim incidence here has broadly followed the legal climate. There was a large spike in notifications up to the start of the legal challenges in 2005. Since then notifications have fallen sharply.

The pattern of reporting for the period 2004-2008 broadly followed the "low" projection from the 2004 paper which had a lower peak and a faster drop-off than given in the "medium" projection shown above. Due to a high level of nil claims in the 2004-2007 notification years relating to pleural plaques, the average cost of claims was also some way below the medium projection.

The total number of claims for the period were c.25,000 compared to a medium projection of $c .55,000$ (the low projection suggested $c .18,000$ ). The average cost for the period has been very volatile due to the issues surrounding pleural plaques, so a comparison to the 2004 projections is not meaningful.

Overall, the actual incurred costs of pleural plaques and pleural thickening claims for the period 2004-2008 have been much lower than the 2004 projection. The 2004 paper gave a range of $£ 202 \mathrm{~m}-£ 932 \mathrm{~m}$, compared to the current incurred costs of $£ 147 \mathrm{~m}$ for the same period.

No further comment is made on pleural plaques here. See Section 8.4 for details of the current legal situation in respect of pleural plaques.

### 3.4.5. Pleural Thickening

Pleural thickening claims were not split out separately in the 2004 data, therefore the graph below does not include a comparison with the 2004 projections.

The number of pleural thickening claims has increased substantially since 2002 but remains at a relatively stable level between 400 and 600 claims per annum. Average costs currently sit in the range of $£ 15 k-£ 20 \mathrm{k}$ per insurance claim.

Figure 7: Pleural Thickening Average Costs and Claims Notified

### 3.5. Aggregate Claim Amounts

The following graph shows the average cost of non-nil settled claims for each claim type over the period 2003-2008. These figures have been referred to in the sections above and can be compared to the modelled average costs used in Section 6 and Sections 8.1 to 8.3 as they can be a better indicator of the underlying trends than the average incurred costs by notification year provided in Section 3.4, where the average incurred costs by notification year are potentially distorted by changes in the rate of nil claims and uncertainty due to future claim development.

Figure 8: Average Settlement Costs for non-nil Claims

The following charts show how the Insurance Market's incurred, paid and outstanding claims break-down between the claim types and notification year. These figures are dominated by the cost of mesothelioma claims.

Figure 9: Claims Incurred by Claim Type

Figure 10: Claims Paid by Claim Type

Figure 11: Claims Outstanding by Claim Type

The following table summarises the total costs implied by the 2004 and 2009 surveys by claim type for various periods from 1990.

Table 4: Comparison of Total Cost by Claim Type 2004 and 2009 Surveys

| $£ m$ | 2004 Survey / Projection |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Period | Mesothelioma | Asbestosis | Lung <br> Cancer | Pleural <br>  <br> Pleural Plaques | Total |
| $1990-1994$ | 119 | 85 | 11 | 10 | $\mathbf{2 2 7}$ |
| $1995-1999$ | 190 | 97 | 13 | 50 | $\mathbf{3 5 0}$ |
| $2000-2003$ | 277 | 125 | 13 | 202 | $\mathbf{6 1 7}$ |
| $2004-2008$ projected | 417 | 174 | 21 | 657 | $\mathbf{1 , 2 6 9}$ |
| Total 1990-2008 | $\mathbf{1 , 0 0 4}$ | $\mathbf{4 8 2}$ | $\mathbf{5 9}$ | $\mathbf{9 1 9}$ | $\mathbf{2 , 4 6 3}$ |

| $£ m$ | 2009 Survey |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Period | Mesothelioma | Asbestosis | Lung <br> Cancer | Pleural <br>  <br> Pleural Plaques | Total |
| $1990-1994$ | 101 | 77 | 9 | 9 | $\mathbf{1 9 6}$ |
| $1995-1999$ | 246 | 109 | 13 | 47 | $\mathbf{4 1 5}$ |
| $2000-2003$ | 391 | 96 | 17 | 131 | $\mathbf{6 3 5}$ |
| $2004-2008$ | 924 | 174 | 58 | 147 | $\mathbf{1 , 3 0 3}$ |
| Total 1990-2008 | $\mathbf{1 , 6 6 2}$ | $\mathbf{4 5 7}$ | $\mathbf{9 7}$ | $\mathbf{3 3 3}$ | $\mathbf{2 , 5 4 9}$ |

The table shows that at a total level the projections for 2004-2008 were close. However, this disguises the deviations in experience for mesothelioma and pleural plaques which have moved in the opposite direction.

## 4. Mesothelioma Population Projections

### 4.1. Summary

The 2004 Working Party paper took as its foundation the HSE study "Mesothelioma Mortality in Great Britain: Estimating the Future Burden" (HSE 2003). This study was expanded upon in the 2005 paper "The expected burden of mesothelioma mortality in Great Britain from 2002 to 2050" (HSE 2005). In 2009 the HSE engaged the HSL (an agency of the HSE) to re-parameterise the model using the latest deaths data and population projections. These updated projections can be found in the HSL research report entitled "RR728 - Projection of mesothelioma mortality in Great Britain" (HSL 2009). The HSL reconstructed the model in a more flexible computer environment which allowed more efficient fitting to the historical data and a fuller exploration of the model's adequacy. This model was parameterised using a number of optimisation techniques, and this led to a new profile of the collective British population's exposure to asbestos.

The structure of the HSL model remains basically the same as the one in the 2003/5 HSE papers, except that the HSL have made an explicit allowance for 'background' mesothelioma deaths. The HSL define these as deaths that would have occurred in the absence of any industrial exploitation of asbestos in Britain. Note these are different to deaths arising from "background" asbestos exposures such as environmental exposures occurring as a consequence of the industrial use of asbestos.

The model results fit the past data well, but the future projections are very sensitive to slight changes in some of the parameters. The HSL 2009 report highlights that the "updated model provides a reasonable basis for making relatively short-term projections of mesothelioma mortality in Britain, including the extent and timing of the peak number of deaths. Longer-term predictions are influenced by two additional sources of uncertainty. These are whether the form of the model is valid in the context of the most recent and future exposures; and if the model is valid in such contexts, the uncertainty arising from the particular choice of the population exposure profile beyond 1978."

With this in mind, we have investigated two alternative model structures to gain insight into the key drivers and assumptions for projecting future mesothelioma deaths. The two alternative structures are explained briefly below and in more detail later in the section. The models used are shown to fit the past data well, yet they produce materially different future projections. This is one of the reasons why there is a large range around the estimate of the future cost of mesothelioma-related claims. We consider that the model structure used by the HSE and HSL currently appears to be the most appropriate model structure to use to project future mesothelioma deaths although the Working Party made its own selections for the underlying parameters. The Working Party's alternative model structures produced results above and below the HSL's and the Working Party's selected models. These provide a potential range of outcomes but by no means provide an upper or lower bound. Practitioners may wish to consider or use the alternative model structures depending on the nature of the specific situation.

Figure 12 Comparison of Potential Population Mesothelioma Deaths Projections

For details of the model selected by the Working Party, the reader can turn straight to Sections 4.4 and 4.5. We suggest the results of the alternative model structures are considered, as they provide a useful indication of potential outcomes and therefore illustrate the uncertainty in such long-term projections.

All the models used to estimate future mesothelioma deaths in the population have the form:
mesothelioma deaths $=$ total population X risk structure
The risk structure is fitted using actual past data along with a defined model and fitting technique. The population, where relevant, is taken from the Office for National Statistics ("ONS") projections. Hence the population projections have a direct impact on the estimated mesothelioma deaths.

Since the 2003/5 HSE Papers were published one of the most relevant changes has been in the UK population projections. Improving longevity and more recent data on immigration and emigration indicate increased population numbers in the ONS' mid-2006 population estimates. While net migration has little impact on the projections, improved longevity has led to increases in the number of deaths projected by the HSL model. The HSL projections are made by applying predicted future mesothelioma death rates to these projections of the British population. A large component of the increase in the long term predicted mesothelioma deaths in the HSL 2009 results compared with the HSE 2003/5 results is caused by the use of these updated population projections.

The HSE and HSL projections are shown below together with the latest actual mesothelioma deaths in Great Britain. The dotted line shows the impact of using the HSE 2003/5 nonclearance assumptions but using the updated ONS mid-2006 population estimates.

Figure 13: HSE and HSL Mesothelioma Death Projection Comparison

## Alternative model structures

Firstly, we have developed a "latency model" based upon the amount and timing of past asbestos imports. By combining this historical import data with estimates for the relative risk of each type of asbestos (blue, brown and white), its usage and the latency period, it is possible to derive projected future numbers of mesothelioma deaths.

The latency model follows a common sense approach and is based on only a few "real world" inputs. By setting some reasonable assumptions it is possible to achieve a good fit to the historical data. However, the model is very sensitive to these choices which are substantially judgemental. The projected number of future deaths could easily be overstated or understated.

Because of its simple structure, the latency model approach implicitly assumes that the future population has the same composition as the underlying population of the past. There is no way to vary the future population to allow for the effects of changes in birth or death rates, or for the impact of immigration and emigration. For this reason the latency model may tend to underestimate the number of future mesothelioma deaths. The model is useful as an easily understandable alternative and the projection is useful as a possible low scenario.

As another alternative model the Working Party has used a simple "birth-cohort model" which projects death rates split by year of birth cohort into future years and applies the rates to an assumed future population.

Professor Julian Peto (Cancer Research UK Chair of Epidemiology at the London School of Hygiene \& Tropical Medicine) has produced projections using models of this type and most recently presented some results at the University of Melbourne on 22 April 2008. He has also previously published papers on mesothelioma population projections using simple age and birth cohort models: "The European mesothelioma epidemic" (Peto et al, 1999) and "Continuing increase in mesothelioma mortality in Britain" (Peto et al, 1995). Prof. Peto found that rates of mesothelioma in men formed a clear pattern when split by age and date of birth. Death rates were seen to increase steeply with age. Additionally, when rates for different birth cohorts are compared, the rates increase across the cohorts until cohorts born in the late 1940's and then rates start to fall.

Apart from the introduction of 'population' considerations, the structure of the birth-cohort model is broadly analogous to the latency model: where increases in the death rates for successive ages can be thought of as being equivalent to the latency period assumption; and the birth cohorts' relative risk factors are analogous to the import data, relative asbestos risk and usage assumptions (i.e. higher relative risk factors for birth cohorts of working age during periods of higher import levels and subsequent usage). Then by applying death rates to the explicitly defined population an additional degree of flexibility is added to the projection of future deaths.

The simple birth-cohort model's projections rely heavily on the future population projections, and as the selection of factors and fitting of the model is not straightforward, there is considerable model and parameter error. It is difficult to quantify the uncertainty in the results but it is fair to say that the death rates are highly dependent on the selected risk relativities. Using the fit implied by Prof. Peto's work and the same population data as the HSL model shows that the birth-cohort model overestimates the number of deaths for 2008. However, we consider that the projections made using a simple birth-cohort approach are useful to illustrate possible high scenarios, and hence we have considered alternative parameterisations.

A key assumption behind the birth cohort model is that the development of death rates by age is constant for each birth cohort. However, the death rates are observed to increase at different rates for different birth cohorts (see section 4.3). Hence this model may not be the most appropriate structure.

The latency and simple birth-cohort models are attractive because of their relative simplicity but by construction they are unable to capture some of the key characteristics of the historical mesothelioma deaths data. In particular they are unable to allow for the observed differences in the development of death rates between birth cohorts. Further, the latency model does not allow for a changing population mix. Although the HSL model is more complex, the additional complexity allows greater flexibility and the ability to better reflect the observed characteristics of the historical data. This should then provide a more credible platform on which to build the projection of future deaths. This also means that the practitioner needs to be fully aware of his/her own choices for the various inputs and parameters of the HSL model and the sensitivities around them.

In the following sections, we explain each of the latency model, the simple birth-cohort model and the HSL models in more detail.

### 4.2. Latency Model

### 4.2.1. Summary

This model uses a simple approach using data based on actual asbestos imports and assumes this is the best indicator of past exposure. The development of this model adds an additional methodology to our toolkit, although the projected mesothelioma deaths were low in comparison to the other methods used.

The simplistic approach makes it easy to use but is highly judgemental. The model assumes no change in population structure or volume: immigration and emigration are not factored in, the structure by age is assumed to be constant as are the death rates by year of birth cohort.

The limitations of the model make it a useful comparison to other models but it has not been selected by the Working Party as the chosen approach.

Below we describe the structure used, results, sensitivities, the strengths and limitations. A spreadsheet copy of the model is available with this paper - see Appendix C for details.

### 4.2.2. Background

When predicting the future number of mesothelioma deaths, use is almost always made of complex statistical models. Their parameterisation by the practitioner is a time-consuming exercise as a deep understanding of those models is required first. This comprehensive learning exercise may imply a full deconstruction of the model and a myriad of tests to get a full understanding of the drivers and sensitivities. Also, in terms of communication with a nontechnical audience their complexity may limit the buy in.

In this section we develop a simple approach to tackle the issue of predicting the future mesothelioma deaths. This simple model aims to provide a different angle to the problem and will almost certainly suggest a different answer in terms of quantum.

By simple, we mean more straightforward but we don't mean simplistic. The number of key parameters will be limited as much as possible and connected with tangible variables.

The underlying reasoning is common sense:

- Developing mesothelioma is almost certainly the result of having been exposed to asbestos in the past. Assuming asbestos imports are the best proxy to map past exposure, the relationship between past imports and actual deaths may come down to shifting the exposure curve with a lag.
- Blue asbestos - Crocidolite - is considered the most hazardous form of asbestos and considered to have the greatest association with asbestos-related diseases followed by Amosite (brown asbestos), and, finally, Chrysotile (white asbestos). The view that some differentials in health hazard exist is supported through several scientific papers about the bio-persistence of the asbestos fibres ${ }^{5}$. Assuming the breakdown of imports between asbestos types is available we can use this information in our model.
- The pure latency period of mesothelioma is the duration between exposure and diagnosis of the disease. Mesothelioma latency is usually estimated as being anywhere between 15 and 50 years, although there have been cases in which the mesothelioma cancer latency was as short as five years and as long as over 50 years after the exposure to asbestos

[^2]occurred. The latency period might depend on both the level and the duration of exposure, leading therefore to a very large range of potential values.

- Exposure to asbestos during a specific year is the consequence of using a fraction of the asbestos imported in that year, but also the result of using the raw materials imported a few years before. The total exposure in a specific year would therefore be a cumulative function of imports during prior years and imports of the current year.
- The total time from first exposure to developing symptoms can therefore be broken down between a usage period and a "pure" latency of developing mesothelioma since exposure.

The underlying idea is therefore to use data about actual imports, broken down by type of asbestos, as the best indicator of past exposure. The latency model consists of developing a simple mathematical relationship between this past exposure and the pattern of deaths observed since the mid 1990s.

As for most of prediction models, the goodness of fit was measured by the sum of squared differences between the predicted and the actual numbers of mesothelioma deaths.

### 4.2.3. Detail of structure

## Asbestos imports

As already mentioned in the previous section, use was made of data about past imports broken down by type of asbestos. This data is available on the Asbestos Information Centre website:

## http://www.aic.org.uk/Asbestos imports.htm

The AIC is an independent organisation that provides advice on managing asbestos containing products in buildings to keep the fibre release to a minimum. Quantities imported since 1940 are part of this publicly available information.

Data provided by the AIC is not complete as many past years have no official records of asbestos imports. To overcome this problem we simply assumed that the increase or decrease in imports between two dates was evenly spread between consecutive years.

Data points for 1920 and 1930 have been added from a volume published recently by the US Geological Survey ${ }^{6}$. This volume has lots of statistics about the worldwide production and consumption of asbestos in the last century; this includes estimates of the UK's apparent consumption at various time intervals.

The following graph illustrates how the imports spread over time. Note that the brown/blue asbestos imports use the left hand scale, the right hand scale is for white asbestos only.

[^3]Figure 14: Asbestos Imports by Type

Tonnage of asbestos imported into the UK from 1920

The white asbestos imports largely outweigh the brown and blue asbestos imports. The blue asbestos imports start to drop from the mid 50s whereas white/brown asbestos imports decrease from the mid 70s only.

## Risk adjusted index

Several medical publications support the existence of risk relativities between the three main types of asbestos. Their conclusion is invariant: brown and blue asbestos are more toxic than white asbestos. As the split of exposure between white/brown/blue is available we integrated this information in our model. We define a risk adjusted index which is simply a weighted average per year of import, the weights being the risk relativities between white, brown and blue asbestos. For a specific year $i$ and a specific type of asbestos the risk adjusted index is defined as:
$R A I_{i, \text { type of asbestos }}=$ imports $_{i, \text { type of asbestos }} \times$ risk relativity factors ${ }_{\text {type of asbestos }}$

## Unscaled deaths index

This stage involves the calculation of an index by type of asbestos using the risk adjusted index. For a specific year of observation $i$ this index is calculated as:

Unscaled deaths $_{i, \text { Type of asbestos }}=\frac{1}{U+1} \cdot \sum_{j=i-L-U}^{i-L} R A I_{j, \text { type of asbestos }}$
With L: latency in years
U: usage period in years
The idea behind this formula is that the asbestos imported in the year $i-L-U$ will generate a cumulative impact of $1 /[U+1]$ per year over the $U$ following years. For instance, assuming a latency of 30 years and a usage period of 10 years, the unscaled index for 1990 will be impacted by $1 / 11^{\text {th }}$ of the asbestos tonnage imported each year from 1950 to 1960 . Similarly the unscaled index for 1991 will be impacted by $1 / 11^{\text {th }}$ of the asbestos tonnage imported each year from 1951 to 1961, and so on.

For a specific year of observation $i$ the total number of unscaled deaths is then:
Unscaled deaths $_{i}=$ Unscaled deaths $i_{i, \text { white asbestos }}+$ Unscaled deaths $i_{i, \text { brown asbestos }}+$ Unscaled deaths ${ }_{i, \text { blue asbestos }}$

## Scaled deaths index

We now need to scale the index as calculated above to the actual number of deaths. This adjustment provides comparable numbers between projected deaths and actual deaths:

$$
\text { Scaled deaths index }_{i}=\frac{\sum_{\text {Base period }} \text { actual number of deaths }}{\sum_{\text {Base period }} \text { unscaled deaths index }} \times \text { unscaled death index }_{i}
$$

The base period is usually the last few years of actual data.

## Goodness of fit

Finally, as for any prediction model, we minimized the squared differences between the projected and actual numbers to get the best fit.

## Key assumptions

Based on the previous section the key assumptions to be calibrated are:

## 1. The risk relativities between white, brown and blue asbestos

Although several publications conclude that brown and blue asbestos are greater health hazards than white asbestos, quantifying relativities is not obvious. The paper The Quantitative Risks of Mesothelioma and Lung Cancer in Relation to Asbestos Exposure by John T. Hodgson and Andrew Darnton suggest a ratio 1:100:500 for chrysotile (white), amosite (brown) and crocidolite (blue) respectively. However using those highly differentiated factors gives a fairly bad fit. We suspect that the 1:100:500 ratios, even if they were fully reliable at an individual level are not really suitable for epidemiological projection purposes, and hence alternative risk relativities may be appropriate.
2. The latency period by type of asbestos between exposure to asbestos and diagnosis

There is no clear scientific consensus as to what the latency period should be. Mesothelioma latency is usually estimated as being somewhere between 15 and 50 years, although there have been cases in which the mesothelioma cancer latency was as short as five years and as long as over 50 years after the exposure to asbestos occurred. We have selected a latency period that provided the best fit (see below).
3. The usage period by type of asbestos

Once again, there is no clear cut scientific opinion as to how long the usage period should be. However we have assumed that it is reasonable for a few years delay between the imports of raw asbestos and their transformation into manufactured products.

### 4.2.4. Analysis of results

It has been possible to find a combination of inputs, which are not unreasonable, that minimise the squared differences between the predicted and actual number of deaths:

Figure 15: Mesothelioma Projections Using the Latency Model

The main curve (with triangle markers) represents this best estimate fit using the latency model in a deterministic manner. We also display in the graph above the $30^{\text {th }}, 70^{\text {th }}$ and $90^{\text {th }}$ percentile using a log normal distribution for the latency periods by type of asbestos. This illustrates the range of potential outcomes for fixed parameters of risk relativities and usage periods. The best estimate scenario corresponds to the mean which also corresponds approximately to a $60^{\text {th }}$ percentile.

For this best estimate scenario the corresponding parameters are:
Table 5: Latency Model Parameters
Risk relativities between types of asbestos

| Crocidolite | 20 |
| :--- | :---: |
| Amosite | 16 |
| Chrysotile | 1 |

Latency periods by type of asbestos (years)

| Crocidolite | 44 |
| :--- | :--- |
| Amosite | 30 |
| Chrysotile | 44 |

Usage periods by type of asbestos (years)

| Crocidolite | 32 |
| :--- | :--- |
| Amosite | 30 |
| Chrysotile | 10 |

| Scaling factor |  |
| :--- | :---: |
| Scale factor | $0.39 \%$ |
| Scale from | 1999 |
| Scale to | 2008 |

Resulting projections

| Number of projected deaths 2009-2050 | 36,557 |
| :--- | :---: |
| Sum of squares (goodness of fit) | 848.0 |
| 2007-2050 deaths / 2007 deaths | 20.21 |
| Peak Deaths | 1,862 |
| Year of Peak | 2009 |

It is worth noting the fairly long usage periods resulting from this fit, although they are not unreasonable. A better fit may be achieved with a different combination of parameters that are also not unreasonable. The best estimate scenario defined above is one amongst several possible best estimate parameterisations.

### 4.2.5. Sensitivities

It should be made clear that the model is very sensitive to the inputs. Small changes in the assumptions have a large impact on the projections, and particularly on the fit of the model. This is illustrated in the tables below where only the inputs highlighted are flexed. All other assumptions are kept as per the base scenario.

Table 6: Risk Relativities

|  | Scenarios |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
| Risk relativities | Best Estimate | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ |
| Crocidolite (blue) | 20 | 1 | 500 | 10 |
| Amosite (brown) | 16 | 1 | 100 | 5 |
| Chrysotile (white) | 1 | 1 | 1 | 1 |
| Projected deaths 2009-2050 | 36,557 | 43,929 | 37,442 | 40,177 |
| Peak Year | 2,009 | 2,014 | 2,010 | 2,010 |
| Peak number of deaths | 1,862 | 1,968 | 1,880 | 1,893 |
| Sum of squares | 848 | 14,748 | 5,065 | 3,128 |

Scenario 1 assumes the same risk from each type of asbestos. Results are more conservative compared to the base scenario as the later imports of white asbestos tends to shift the curve of projected deaths further to the right. The fit to actual data is very bad.

Scenario 2 assumes higher risk relativities as per the Hodgson \& Darnton paper. While the projected number of deaths is close to the base scenario, the goodness of fit has deteriorated.

Scenario 3 assumes lower risk relativities than our base scenario. Although the projected number of deaths do not differ much compared to Scenario 2, the fit to the actual numbers of deaths is somewhat better.

Table 7: Latencies

|  | Scenarios |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
| Latency periods (years) | Best Estimate | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ |
| Crocidolite (blue) | 44 | 30 | 50 | 20 |
| Amosite (brown) | 30 | 30 | 50 | 20 |
| Chrysotile (white) | 44 | 30 | 50 | 40 |
| Projected deaths 2009-2050 | 36,557 | 23,849 | 117,857 | 18,793 |
| Peak Year | 2,009 | 2,009 | 2,027 | 2,009 |
| Peak number of deaths | 1,862 | 1,694 | 3,879 | 1,460 |
| Sum of squares | 848 | 42,371 | 16,319 | 203,643 |

Unsurprisingly, the higher the latency periods, the higher the number of projected future deaths. This simply results from a greater lag between exposure and death. The varying latency periods result in much worse fits to the actual number of deaths.

Table 8: Usage Periods

|  | Scenarios |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
| Usage periods (years) | Best Estimate | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ |
| Crocidolite (blue) | 32 | 10 | 20 | 40 |
| Amosite (brown) | 30 | 10 | 20 | 40 |
| Chrysotile (white) | 10 | 10 | 20 | 40 |
| Projected deaths 2009-2050 | 36,557 | 15,209 | 26,724 | 59,364 |
| Peak Year | 2,009 | 2,009 | 2,009 | 2,018 |
| Peak number of deaths | 1,862 | 1,443 | 1,726 | 1,959 |
| Sum of squares | 848 | 22,692 | 2,463 | 4,506 |

The sensitivities are similar to those the for latency periods. The longer the usage period, the higher the number of projected future deaths. This simply results from a greater lag between exposure and death.

### 4.2.6. Strengths and Limitations of the Model

The model has the following strengths:

- Common sense approach based on a few "real world" inputs.
- We can achieve a good fit to the actual numbers of deaths by combining reasonable assumptions.
- Stochastic modelling can easily be implemented by sampling the key parameters.

As regards to limitations we highlight the following:

- As illustrated in the previous section, the latency model is very sensitive to the inputs. The number of future deaths can then easily be understated / overstated by a large amount.
- ....and the selection of the key assumptions remains a very judgmental exercise.
- The latency model has some implicit assumptions about the underlying population: it is assumed to be constant in structure: age, volume (i.e. no changes in emigration/immigration/mortality/birth rates) for future years which is very doubtful. There is a risk of underestimating or overestimating the future deaths.

### 4.2.7. Uncertainty

As we have seen in this section, the latency model is attractive because of its simplicity. It does not require the practitioner to spend a considerable amount of time to get around it. Also parameters are readily interpretable which is a great advantage when communicating with a non-technical audience. Finally it seems to provide a good fit with a set of inputs that are not unreasonable.

However the main uncertainties are related to its very judgmental calibration. Sensitivities show considerable potential for underestimating / overestimating the number of future deaths. The lack of conclusive evidence for key assumptions is a strong limitation when calibrating this model. As a result the goodness of fit maybe the only criteria to calibrate inputs.

The implicit assumptions about the underlying population are also a strong limitation. The latency model looks at the relationship between a population exposed in the past and shifts the corresponding curve of mesothelioma deaths using lags by type of asbestos. Once the model is correctly fitted to actual deaths it uses the same implicit population for future deaths. It therefore assumes no change in the population structure or volume: immigration and emigration are not factored in, the structure by age is assumed to be constant as are the death rates by year of birth cohort. It doesn't allow for the (possibly non-linear) effect of an aging population.

As we will see later in the paper, the population projections have a large impact on the number of future mesothelioma deaths. Incidence rates by year of birth cohort also have a significant impact and it can be demonstrated on the actual population data that incidence rates effectively differentiate by cohort of birth.

For those reasons we believe the latency model may not have the best structure. However we believe this model is appropriate as a benchmark for the lower end of the projections.

### 4.3. Simple Birth Cohort Model

### 4.3.1. Summary

This model has additional features to the latency model. In particular, it allows for the death rates to vary according to year of birth. Analysis of the actual historical death rate data demonstrated that there are additional features shown by looking at year of birth cohorts in addition to age. To attempt to capture these features, we used a model based on year of birth and age, and hence added an additional methodology to our toolkit.

The results of this approach tended to project mesothelioma deaths that were high in comparison to the other methods used. This is probably due to the one main disadvantage of this method: the model assumes that the rate of change of the death rates by age within each birth cohort is identical. Analysis of the actual historical data shows that this assumption does not hold and is therefore a simplification of reality. This limitation is the reason why the model has not been selected by the Working Party as our chosen approach. However, this model is considered to be a useful comparison to other projection methods.

The model does not have a large number of parameters and so is still a practical approach and maybe useful in other applications where data is very limited. An example of this would be a comparison between worldwide mesothelioma projections.

Below we describe the structure used, the results, sensitivities and the strengths and limitations.

### 4.3.2. Background and structure

Prof. Peto has performed projections using models of this type and, most recently, presented results at the University of Melbourne on 22 April 2008. He has also previously published papers on mesothelioma population projections using simple age and birth cohort models: "The European mesothelioma epidemic" (Peto et al, 1999) and "Continuing increase in mesothelioma mortality in Britain" (Peto et al, 1995). Prof. Peto found that rates of mesothelioma in men formed a clear pattern when split by age and date of birth. Death rates were seen to increase steeply with age. Additionally, when rates for different birth cohorts are compared, the rates increase across the cohorts up to births in the 1940s with reductions in younger cohorts.

Actual mesothelioma deaths by single year of age and year of death (ranging from 1968 to 2006) were provided from the ONS register. They were reclassified into the number of deaths split by age at death and year of birth. Grouping the numbers into five-year bands of age and years of death, death rates per 100,000 were calculated based on historical population figures. ONS mid-2006 population estimates for males in England, Wales and Scotland were used. The graph below shows the death rates by age for the different year of birth cohorts. This illustrates the hypothesis that death rates vary not only by age but also by year of birth.

Figure 16: Actual Death Rates by Age (based on ONS mesothelioma deaths and mid-2006 population estimates)

This feature of varying death rates by year of birth and age led us to consider using a birthcohort model for projecting mesothelioma deaths. We believe that it is useful to understand this approach so that it could be implemented as an alternative methodology.

Prof. Peto has fitted a multiplicative Poisson regression model to the actual number of deaths between 1990 and 2004 (all ages) and from 1970 to 1990 (aged over 60). The actual death rates shown below are those calculated by the Working Party based on the ONS mid-2006 population estimates for males in England, Wales and Scotland. These will be slightly different to those calculated by Prof. Peto as he has used United Nations population statistics for the UK.

Table 9: Actual Death Rates (number of deaths per 100,000 of population)

| Age | Year of birth |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | 1930-1934 | 1935-1939 | 1940-1944 | 1945-1949 |
| $35-39$ | 0.13 | 0.11 | 0.30 | 0.31 |
| $40-44$ | 0.32 | 0.66 | 0.80 | 0.89 |
| $45-49$ | 1.22 | 1.62 | 2.33 | 1.93 |
| $50-54$ | 2.71 | 4.14 | 5.05 | 3.96 |
| $55-59$ | 6.42 | 8.06 | 9.09 | 6.65 |
| $60-64$ | 11.26 | 14.31 | 13.65 | N/A |
| $65-69$ | 19.09 | 19.54 | $\mathrm{~N} / \mathrm{A}$ | N/A |
| $70-74$ | 26.36 | N/A | N/A | N/A |
| $75-79$ | N/A | N/A | N/A | N/A |
| $80-84$ | N/A | N/A | N/A | N/A |
| $85-89$ | N/A | N/A | N/A | N/A |

The death rate $r(i, j)$ in age-group $i$ and birth cohort $j$ was fitted to the number of deaths $n(i, j)$ and population $p(i, j)$ such that:
$r(\mathrm{i}, \mathrm{j})=\mathrm{n}(\mathrm{i}, \mathrm{j}) / \mathrm{p}(\mathrm{i}, \mathrm{j})=\mathrm{a}(\mathrm{i})^{*} \mathrm{c}(\mathrm{j})$
Where $a(i)$ is the age-specific rate for age group $i$, and $c(j)$ is the birth cohort specific relative risk for birth cohort j.

Following discussions with Prof. Peto in respect of his fitted death rates using the Poisson regression model, we analysed the fitted death rates and then selected risk relativities between each of the age groups and birth cohorts. These were based on the average ratio calculated between each birth cohort and each age group separately.

The death rate for one particular combination of age-group i and birth-cohort j was fixed and this enabled a table of death rates to be constructed.

The model structure contains death rates for 5-year bands for each age at death and year of birth. This forms a grid of death rates, as shown in the example in the table below. Also shown are the risk relativities that were applied to either construct the death rate for one age group or for one year of birth cohort along the grid.

Table 10: Fitted Death Rates (number of deaths per 100,000 of population)

| Age | Year of birth |  |  |  | Risk relativity (birth cohort) |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1910-1914 | 1915-1919 | 1920-1924 | 1925-1929 |  |
| 35-39 | 0.06 | 0.09 | 0.14 | 0.20 | 294\% |
| 40-44 | 0.18 | 0.28 | 0.42 | 0.60 | 214\% |
| 45-49 | 0.39 | 0.59 | 0.89 | 1.28 | 201\% |
| 50-54 | 0.79 | 1.19 | 1.80 | 2.57 | 185\% |
| 55-59 | 1.46 | 2.21 | 3.33 | 4.77 | 171\% |
| 60-64 | 2.51 | 3.79 | 5.70 | 8.17 | 169\% |
| 65-69 | 4.26 | 6.42 | 9.67 | 13.85 | 166\% |
| 70-74 | 7.07 | 10.65 | 16.05 | 22.99 | 161\% |
| 75-79 | 11.41 | 17.20 | 25.91 | 37.13 | 143\% |
| 80-84 | 16.31 | 24.58 | 37.03 | 53.06 | 139\% |
| 85-89 | 22.65 | 34.13 | 51.42 | 73.69 | 294\% |
| Risk relativity (age) | 129\% | 117\% | 126\% | 89\% |  |

The fitted numbers of deaths are then calculated by multiplying these rates by the population estimate for the applicable age group and birth cohort. ONS mid-2006 population estimates have been used, which is consistent with the other models set out in this paper.

In order to project deaths in future years, the numbers are then transposed to the applicable years of death. A result of this model structure is that the development of death rates is constant across year of birth cohorts.

The following three tables show an example of the population figures and projected deaths based on the years of birth highlighted above. The population estimates are from 1968 onwards and therefore the earliest ages and years of birth are truncated in the tables below. However, this does not have an impact on projections of future mesothelioma deaths.

Table 11: Population in 000's (ONS mid-2006 estimates)

| Age |  | Year of birth |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1910-1914 | 1915-1919 | 1920-1924 | 1925-1929 |  |  |
| $35-39$ | N/A | N/A | N/A | N/A |  |  |
| $40-44$ | N/A | N/A | N/A | 6,230 |  |  |
| $45-49$ | N/A | N/A | 6,773 | 8,087 |  |  |
| $50-54$ | N/A | 5,357 | 8,803 | 7,816 |  |  |
| $55-59$ | 6,101 | 6,879 | 8,299 | 7,424 |  |  |
| $60-64$ | 7,326 | 6,240 | 7,595 | 6,867 |  |  |
| $65-69$ | 6,273 | 5,406 | 6,659 | 6,111 |  |  |
| $70-74$ | 4,980 | 4,362 | 5,484 | 5,151 |  |  |
| $75-79$ | 3,550 | 3,217 | 4,145 | 4,049 |  |  |
| $80-84$ | 2,180 | 2,079 | 2,790 | 2,904 |  |  |
| $85-89$ | 1,074 | 1,106 | 1,607 | 1,829 |  |  |

Table 12: Projected Deaths (000's) by Year of Birth Cohort

| Age | Year of birth |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1915-1919 | 1920-1924 | 1925-1929 |  |  |
| $35-39$ | N/A | N/A | N/A | N/A |  |
| $40-44$ | N/A | N/A | N/A | 37 |  |
| $45-49$ | N/A | N/A | 61 | $\mathbf{1 0 4}$ |  |
| $50-54$ | N/A | 64 | $\mathbf{1 5 8}$ | 201 |  |
| $55-59$ | 89 | 152 | 276 | 354 |  |
| $60-64$ | 184 | 236 | 433 | 561 |  |
| $65-69$ | 267 | 347 | 644 | 846 |  |
| $70-74$ | 352 | 465 | 880 | 1,184 |  |
| $75-79$ | 405 | 553 | 1,074 | 1,503 |  |
| $80-84$ | 355 | 511 | 1,033 | 1,541 |  |
| $85-89$ | 243 | 377 | 826 | 1,348 |  |

The diagonals of the year of birth table map to a 5-year band of years of death.
Table 13: Projected Deaths (000's) by Year of Death

| Age | 1965-1969 | Year of death <br> 1970-1974 |  |
| :---: | :---: | :---: | :---: |
| $35-39$ | 16 | 25 | 32 |
| $40-44$ | 37 | 61 | 71 |
| $45-49$ | 61 | $\mathbf{1 0 4}$ | 127 |
| $50-54$ | 64 | 158 | 201 |
| $55-59$ | 89 | 152 | 276 |
| $60-64$ | 85 | 184 | 236 |
| $65-69$ | 79 | 161 | 267 |
| $70-74$ | 36 | 133 | 207 |
| $75-79$ | 21 | 52 | 144 |
| $80-84$ | 12 | 23 | 41 |
| $85-89$ | 6 | 9 | 13 |

Deaths were projected for age groups from 35-39 to 85-89 and year of death cohorts from 19601964 to 2045-2049.

### 4.3.3. Results

Results of these initial projections are shown below, together with the actual mesothelioma deaths. The modelled deaths are approximately estimated by individual year, although the model used 5 -year age bands. The modelled deaths have been allocated using an approximate method to individual future years and therefore the projections do not look smooth.

Figure 17: Initial Fit of Simple Birth Cohort Model Male Mesothelioma Deaths projection

It appears that this fitted model tends to over project in the years post 2002. Therefore, alternative risk relativities between each of the age groups and birth cohorts have been selected to improve the fit in these later years (see Sections 4.3.4 and 4.3.5).

## Results for individual birth cohorts

The men born between 1930 and 1940 appear to have the highest risk of developing mesothelioma (as shown in the graph of actual death rates at the start of Section 4.3.2). This is because the first 10 to 20 years of their working lives coincided with the peak of asbestos imports into the UK. Examples of the death rates for one of these birth cohorts and a later cohort are shown below, together with a comparison to actual death rates and those produced by the HSL model covered in Section 4.4.

Figure 18: Projected Death Rate per 100,000 for the 1945-1949 Birth Cohort

Figure 19: Projected Death Rate per 100,000 for the 1930-1934 Birth Cohort

The graphs demonstrate the fit to past data and also the range of uncertainty resulting from the different models.

### 4.3.4. Sensitivities

Prof. Peto has used UN population statistics for the UK, which is slightly different to that used by the Working Party (ONS mid-2006 population estimates for males in England, Wales and Scotland). Therefore there is some uncertainty around the suitability of Prof. Peto's fitted death rates to the Working Party's mesothelioma modelling. For this reason, we have investigated alternative parameterisations of the model.

We have considered some alternatives to illustrate the sensitivity of the results to the underlying parameters. The key parameters are:

- the risk relativities between adjacent cohorts (age group and year of birth)
- the death rate for one particular combination of age-group i and birth-cohort j

By changing one risk relativity ratio at a time, a slightly better fit can be obtained. An example of this is given by changing the selected relativity between the 1945-1949 and the 1950-1954 birth cohorts from (24.8\%) to (22.5\%). This produces a better overall fit to the past data. The following graph shows the results of the selected fit compared to this sensitivity test.

Figure 20: Male Mesothelioma Deaths (ages 30-89) - Initial Fit and Sensitivity Test

### 4.3.5. Alternative scenario

In considering an alternative fit of the model, we have analysed the risk relativities between different cohorts and selected alternative risk relativities to derive a better fit based on effectively minimising the sum of the squares of the difference between the actual observations and the modelled observations. The fit is therefore based on a judgemental analysis and comparison to other possible relativities.

The graph below shows those average risk relativities between age at death cohorts from the actual death rates and those risk relativities selected within the initial fit together with the alternative selections.

Figure 21: Risk Relativities for Adjacent Age Groups

The following graph shows those average risk relativities between birth cohorts implied from the actual death rates, those risk relativities selected within the initial fit, approximate relativities implied from the latency model, together with the alternative selections. The latency model gives a useful alternative view, in particular a greater decreasing trend for more recent birth cohorts. The alternative selection takes some account of this.

Figure 22: Risk Relativities for Adjacent Birth Cohorts

The following graph shows the results of the initial fit compared to this alternative fit. We note that the results are sensitive to the risk relativities selected and can produce a large range of results. This is one of the reasons why the Working Party has not selected this model structure. The alternative fit is also above the HSL projection (see Section 4.4).

Figure 23: Male Mesothelioma Deaths (ages 30-89) - Initial and Alternative Fits

### 4.3.6. Strengths and limitations

## Strengths:

The birth cohort model has a reasonably simple structure and is therefore easy to understand and communicate. Another advantage is that the split by year of birth cohort means that the relative differences between the cohorts are allowed for, unlike in the latency model.

This model is particularly useful where detailed data is not available; for example Prof. Peto has used this kind of model for mesothelioma projections for other countries worldwide.

## Limitations:

A key assumption behind the birth cohort model is that the development of death rates by age is constant for each birth cohort. This refers to the rate of change of the death rates and not the absolute values. The death rates increase within a year of birth cohort as the population ages. Analysis of the data shows that this trend in death rates varies by year of birth cohort. This is demonstrated by the following graph.

Figure 24: Development of Death Rates between Age Bands and Adjacent Year of Birth Cohorts

The relative death rates between each 5-year age band have been calculated, based upon actual data, for each birth cohort. These have then been compared between year-of-birth cohorts. If the change in death rate from one age band to the next is the same in adjacent birth cohorts, then a result of zero is obtained. Where a different trend is observed in adjacent birth cohorts, then a result either above or below zero is obtained. This will then show an increasing or decreasing trend along the adjacent birth cohorts.

The bold line lying on the x-axis shows the assumed development trend in the simple birth cohort model - that the relative trend in death rates between age bands does not vary by birth cohort. The variation arising out of the actual data shows that there is a changing relationship between the development of death rate by age in different birth cohorts.

The latency model also does not capture this feature. The latency and birth cohort models may therefore not be the best structures to use.

Other limitations to this approach include:

- The projections rely heavily on the future population projections and the assumptions relating to mortality improvement, immigration and emigration (similarly to the HSL model).
- Entries in the table of death rates include some ages and cohorts with very low numbers of observed deaths. The presence of background deaths can 'swamp' those cells with low observed values and therefore the projections from these calculations may not be credible.
- The selection of factors and fitting of the Poisson model is not straightforward. It is difficult to quantify the uncertainty in the model results but it is fair to say that the death rates are highly dependent on the selected risk relativities.
- The observations for the youngest and oldest deaths in each birth cohort are incomplete, as well as the second youngest and oldest cells. The projections are largely dependent on the more recent incomplete cohorts, which is the case for most projection models.

Given the above limitations, and the potential for the method to over-project as a result of these limitations, the Working Party considers that the model may not have the best structure. However, with care, it could be useful as a potential high scenario. The future experience will demonstrate the effectiveness of the model, and hence the model's predictive performance should be monitored.

### 4.4. HSE/HSL Model

The 2004 Working Party paper took as its foundation the HSE study "Mesothelioma Mortality in Great Britain: Estimating the Future Burden" (HSE 2003). This study was expanded upon in the 2005 paper "The expected burden of mesothelioma mortality in Great Britain from 2002 to 2050" (HSE 2005).

In 2009 the HSE engaged the HSL to parameterise the model they had used for updated actual population deaths data as at 2006 and the latest population projections. These updated projections can be found in the 2009 HSL research report entitled "RR728 - Projection of mesothelioma mortality in Great Britain" (HSL 2009), and are also summarised on the HSE statistics webpage at http://www.hse.gov.uk/statistics/causdis/mesothelioma/burden.htm.

The HSL's work involved a reconstruction of the model in a more flexible computer environment that has allowed more efficient fitting to historical data and fuller exploration of the model's adequacy. The HSL have used a number of optimisation techniques (MATLAB's fminsearch function and the Metropolis-Hastings algorithm, a Markov Chain Monte Carlo technique) to parameterise the model and this process revealed a profile over time of the collective population exposure to asbestos in more detail than was possible in previous analyses. The HSL, like the HSE, parameterised the model by minimising the deviance residual (the sum of the square of actual less fitted, divided by the fitted) by age and year of death.

The HSL projections result in a peak number of male mesothelioma deaths aged between ages 20 to 89 in 2016 of $1,990^{7}$, and a total of 2,038 for all ages. This is three years later than the peak of the previous HSE projections and represents approximately $8 \%$ more deaths at the peak. 2009 and post, the HSL project approximately $23 \%$ more deaths than the 2003/5 HSE projections. The increase in the number of deaths projected by the HSL is predominantly due to the change of two parameters:

[^4]- The improving longevity and more recent data on immigration and emigration indicating increased population numbers in the ONS mid-2006 population estimates ${ }^{8}$; and
- The increase in the assumed exposure between 1978 and 2000.

### 4.4.1. Structure

The structure of the HSL model remains basically the same as the model used in the 2003/5 HSE projections, except that the HSL have made an allowance for background mesothelioma deaths. Background deaths are deaths that would have occurred in the absence of any industrial exploitation of asbestos in Britain. Note these are different to deaths arising from "background" asbestos exposures such as environmental exposures occurring as a consequence of the industrial use of asbestos. The HSL assume that this background rate is between 1 to 2 per million per year; which equates to approximately 20 to 35 background deaths a year.

The formula used by the HSL for estimating the number of mesothelioma deaths at age A, in year $T\left(F_{A, T}\right)$ is:

$$
F_{A, T}=\frac{\left[\sum_{l=1}^{A-1} W_{A-l} D_{T-l} I(l+1-L)^{k} 0.5^{l / H}\right] D_{x_{T}} P_{A, T}\left(M-\sum_{A=20}^{89} \sum_{T=1968}^{2006} B_{A, T}\right)}{\sum_{A=20}^{89} \sum_{T=1968}^{2006}\left[\sum_{l=1}^{A-1} W_{A-l} D_{T-l}(l+1-L)^{k} 0.5^{l / H}\right] D_{x_{T}} P_{A, T}}+B_{A, T}
$$

Where:

- $P_{A, T} \quad=$ The number of people alive (or person-years at risk) at age $A$ in year $T$.
- $W_{A} \quad=$ Age specific exposure potential at age $A$.
- $D_{T} \quad=$ Overall population exposure in year $T$.
- $D_{x T} \quad=$ Proportion of mesothelioma deaths diagnosed in year $T$.
- $L \quad=$ Lag period (in years) before effect starts.
- H = Half life (in years) for clearance of asbestos from lungs.
- $k \quad=$ Exponent of time, modelling the increase of risk of developing mesothelioma with increasing time from exposure.
- $B_{A, T} \quad=$ The total number background deaths for age $A$ in year $T$.
$B_{A, T}=$ background rate ${ }^{*} P_{A, T}$,
these deaths are then allocated to age using the proportion of $I$ * $(A-L)^{k}$.
- $I \quad=$ Indicator variable where $I=0$ if $I<1-L$ and $I=1$ otherwise.
- $I$ = Indexes years lagged from the risk year.
- $M \quad$ The total number of observed mesothelioma deaths to date.

The table below details the parameters used by the HSL in the model using the fminsearch function (Model A).

[^5]Figure 25: HSL Parameter Estimates

| Parameter estimates |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $k$ | 2.47 | Background rate | 1.22 |  |  |  |  |  |  |
| Maximum exposure year | 1963 | Half-life (years) | 1000000 (fixed) |  |  |  |  |  |  |
| Change in exposure index (\% per year) in... | Relative exposure potential by age group |  |  |  |  |  |  |  |  |
| $1898(D(1))$ | 0 (fixed) | 0 to 4 | 0.00 |  |  |  |  |  |  |
| $1908(D(2))$ | 1000 (fixed) | 5 to 15 | 0.00 |  |  |  |  |  |  |
| $1918(D(3))$ | 100000 (fixed) | 16 to 19 | 0.30 |  |  |  |  |  |  |
| $1928(D(4))$ | -92.4 | 20 to 29 | 1.00 (baseline) |  |  |  |  |  |  |
| $1938(D(5))$ | 104.9 | 30 to 39 | 1.79 |  |  |  |  |  |  |
| $1948(D(6))$ | -26.0 | 40 to 49 | 1.54 |  |  |  |  |  |  |
| $1958(D(7))$ | 38.0 | 50 to 59 | 0.07 |  |  |  |  |  |  |
| 1963 | 0 (by definition) | 60 to 64 | 0.33 |  |  |  |  |  |  |
| $1968(D(8))$ | -7.7 | $65+$ | 0.00 |  |  |  |  |  |  |
| $1978(D(9))$ | -16.3 |  |  |  |  |  |  |  |  |
| Projections of future mesothelioma deaths in males aged 20-89 |  |  |  |  |  |  |  |  |  |
| Peak level | 2020 | Peak year | 2016 |  |  |  |  |  |  |
| Deviance |  |  |  |  | Diagnostic trend |  |  |  | - |

In Section 4.4.4 we have set out some of the sensitivities of the model to the key parameters and the differences between the HSE 2003/5 and the HSL 2009 parameters.

### 4.4.2. Results

Similar to the HSE, the HSL have preferred a non-clearance model based on a better goodness of fit to the observed deaths. A non-clearance model assumes (effectively) no clearance of asbestos fibres from the lungs over time i.e. that $H$ is very large.

The HSE 2003/5 and HSL 2009 projections are shown below together with the latest actual mesothelioma deaths in Great Britain. The dotted line shows this impact of using the HSE 2005 non-clearance model assumptions but using the updated ONS mid-2006 population estimates.

Figure 26: HSE and HSL Projections Against Actual Deaths to 2006

### 4.4.3. Strengths and Limitations

## Past fit

The model fits the past data well, but the future projections are very sensitive to slight changes in some of the parameters. The HSL report highlights the following specific limitation:
"the updated model provides a reasonable basis for making relatively short-term projections of mesothelioma mortality in Britain, including the extent and timing of the peak number of deaths. However, longer-term predictions comprise two additional sources of uncertainty which are not captured within the prediction intervals for the annual number of deaths:
a) whether the form of the model is valid for more recent and future exposure contexts; and
b) if the model is valid in such contexts, the uncertainty arising from the particular choice of the population exposure profile beyond 1978."

## Complex structure and number of parameters

As can be seen from the formula of the model, it is quite complex with a considerable number of parameters. This allows the model to be flexible in allowing for different death rates at different ages for different birth cohorts. The key assumption underlying the simple age/birth cohort model is that the ratio of death rates at different ages is identical across all cohorts (equivalently that the ratio of rates between birth cohorts is the same at all ages).
The mesothelioma data until the 1990's fitted the key assumption (of the simple age/birth cohort model) quite closely, but the more recent deaths began to show that the death rates, especially for the most recent birth cohorts, were not behaving consistently. This is the reason why the HSE and Prof. Peto developed this model. Whether different birth cohorts will behave differently in the future is key to understanding whether the model is appropriate to project future deaths.

Although the model fits the past data well, the future projections are very sensitive to slight changes in some of the parameters. It is important to realise that the central HSL projections sit in a wide range and the future number of deaths could easily be higher or lower by a considerable amount.

## Mortality improvements

The model uses Great British population estimates to project the number of mesothelioma deaths. The latest ONS estimates take into account improving longevity and more recent data on immigration and emigration.

The large sample of mesothelioma claims data that the Working Party has collected, see Section 6, illustrates that the exposed population, on average, are experiencing heavier mortality than the Great British population at large.

If the exposed population does not enjoy the same level of improvements in longevity as the population as a whole, then there will be a tendency for the model to over-project the future mesothelioma deaths. This is because, if the mortality differential continues in the future, the exposed population will form a decreasing relative proportion of the overall population. A projected mesothelioma death rate per unit of overall population based on past data applied to an overall future population projection would then tend to over estimate the number of future mesothelioma deaths.

## Immigration and emigration

As highlighted in the previous Working Party paper entitled "UK Asbestos Working Party Update 2008", immigration and emigration in the Great British population estimates potentially affect the number of mesothelioma deaths predicted by the model. Immigration increases the number of mesothelioma deaths predicted by the HSL model as immigration increases the population in the future at old age ranges. If immigrants have been exposed to asbestos outside of Great Britain, they are unlikely to be eligible to make a claim on UK employers' liability policies. Therefore immigration could artificially increase the number of future claims on UK employers' liability policies.

Emigration, on the other hand, decreases the number of mesothelioma deaths predicted by the HSL model as emigrants could have been exposed to asbestos in the UK in the past but will not form part of the UK population estimates from which future deaths are calculated. In this case there is additional uncertainty as to the likelihood that a person emigrating from Great Britain having been exposed to asbestos as part of their employment in Great Britain and then going on to develop mesothelioma, would make a claim on UK employers' liability policies. Therefore emigration has the potential to artificially decrease the number of future claims on UK employers' liability policies.

If net migration is small, the effects of immigration and emigration will broadly cancel each other out in the overall future population estimates. However, without understanding the proportions of people exposed to asbestos and the ages of people entering/leaving Great Britain the effects on future claim numbers are difficult to quantify.

We have looked at the impact of cutting-off the population at a certain time (e.g. post 1990) when the vast majority of exposure to asbestos will have taken place, and then decrementing the remaining population purely for mortality. This eliminates the effect of net migration post the chosen cut-off year, leading to a slight increase in the number of projected deaths. This slightly counter-intuitive result is due to the small but negative migration figures at ages 45 and above embedded in ONS post-1990 data and 2006-based principal projections. See Appendix G and Section 4.4.4 for more details.

Deaths over the age of 80 and continued increase in developing mesothelioma

There is little data to model how the disease may develop at extremely old ages, adding further to the uncertainty of projections in the 80+ category. This age band assumes an increasing importance in the later years of the HSL projections, with more than half of all projected future deaths arising from 80+ year olds after 2023.

As stated in the 2004 and 2008 Working Party papers, the particular uncertainty over the number of deaths in the 80+ category could work two ways. On the one hand, should the increase in mesothelioma incidence rates (to the power of $k$ ) hold for even older ages, when combined with increasing longevity, the number of 80+ year old mesothelioma deaths could become far more significant and increase the number of future mesothelioma deaths above the levels currently predicted by the HSL model. Conversely, if the continuing appropriateness of " $k$ " in the HSL model proves to be an overstatement at older 80+ ages, the future number of mesothelioma deaths could be far lower than currently predicted.

The half-life factor should decrease the risk at old ages. This assumption models the fact that asbestos fibres can be broken down in the lung and removed from the body, and over time this may serve to diminish the propensity to develop mesothelioma. The HSL have set the half-life factor to $1,000,000$, in other words there is deemed to be no half-life effect. Whilst this may be entirely appropriate for younger ages, if there is a half-life effect, clearly this would be more significant for the 80+ year olds.

As an alternative approach to this issue, we have looked at the impact of introducing a cap on the increasing risk implied by the " $k$ " parameter. This has been achieved by reducing the risk after $x$ years from exposure (e.g. where $x=60$ ). Under this assumption an 80 year old's risk, with a ten year lag from first exposure, is calculated as $\left(1^{k}+11^{k}+\ldots+59^{k}+60^{k}+60^{k}+60^{k}+\ldots+60^{k}\right)$ instead of $\left(1^{k}+11^{k}+\ldots+59^{k}+60^{k}+61^{k}+\ldots+70^{k}\right)$ where each component of the formula reflects the contribution to the overall risk from exposure n years ago. The cap reduces the chance of developing mesothelioma after a period of 60+ years. This is best shown in the graphs below, which detail the death rate per 100,000 by 5 year age bands for the 1945-1949 birth cohort, with and without the cap at 60 years. Figure 28 shows the top right hand corner of figure 27 magnified to show the divergence.

Figure 27: Death Rates for 1945-1949 Birth Cohort
Death rate per 100,000 for the 1945-1949 birth cohort

Figure 28: Death Rates for 1945-1949 Birth Cohort (ages 70+ only)

## Deaths over the age of 90

The HSL model only projects deaths in males between the ages of 20 and 89 . This in part recognises the sparseness of the data for the 90+ age band and the uncertainty over the continued appropriateness of the exponential relationship of developing mesothelioma.

The HSL model predicts that approximately $70 \%$ of future deaths will come from the $80+$ age band. The proportion of actual male mesothelioma deaths from the 80+ age band has increased from approximately $9 \%$ in 1990 to $22 \%$ in 2006, as shown in the graph below.

Figure 29: Percentage of Male Deaths

With the new population estimates detailing a greater number of $80+$ year olds, the number of 90+ year old mesothelioma deaths predicted by the HSL model could be significant if it was adjusted to account for ages over 89. The mesothelioma deaths projections in the HSL 2009 paper contain an allowance for deaths at age 90 and higher. This allowance was estimated using a linear trend and contributes about $3 \%$ to the published figure of approximately 61,000 deaths from 2007 onwards. Using other methodologies or extending the HSL model directly to ages 90-95 would likely produce higher estimates, however these should not be considered very reliable, either, due to the above mentioned data and model limitations.

Insurance claims from 80-89 and 90+ year olds are subject to even greater uncertainty, given the propensity of individuals at this age to make a claim as discussed further in Section 5. However, given that average costs tend to be lower, the impact of this issue on overall Insurance Market claims costs will be ameliorated somewhat.

### 4.4.4. Key Sensitivities of Assumptions

Like any model the parameters are subject to uncertainty. In this section we will focus on the following key parameters within the HSL model:

- The half-life and $k$ factor ("Exponent of time, modelling the increase of risk of developing mesothelioma with increasing time from exposure");
- Exposure; and
- The population.

## Half-life and k factor

As highlighted in the previous two Working Party papers entitled "UK Asbestos - The Definitive Guide" and "UK Asbestos Working Party Update 2008", two of the key parameters are the power relationship, $k$, between the time since exposure to asbestos and the development of mesothelioma and the half-life, the number of years it takes for asbestos fibres to clear from the lungs. The half-life and "k" are closely correlated and cannot be independently estimated. In effect reducing the half-life means increasing the value of $k$ and vice versa.

The HSL selected a non-clearance model, like the HSE in 2003/5. This assumes that there is (effectively) no clearance of asbestos fibres from the lungs. Through the statistical methods the HSL have used to parameterise the model they have found that:
a) the fit of the model improved as the half-life was increased; and
b) the half-life is infinitely large and that there is no clearance of asbestos once inhaled.

The HSL have increased the half-life factor (from 1,000 used in the 2003/5 HSE papers) to $1,000,000$. Increasing the half-life will increase the number of deaths estimated by the model. However, since a half-life of 1,000 effectively assumes that no clearance of asbestos fibres occurs, the change the half-life factor has minimal effect on the model.

Independent epidemiological evidence suggests that after a brief exposure to asbestos, the risk of developing mesothelioma increases in proportion to a power of time, probably in the range 2 to 3 . However, there is uncertainty about exactly what value $k$ and the half-life should take. Refitting the model by the HSL led to an estimate of $k$ of 2.47 (slightly lower than the value of 2.6 estimated in the 2003/5 HSE papers). A lower value of the $k$ factor reduced the number of deaths estimated by the model.

There are several studies, including "Sixty years on: the price of assembling military gas masks in 1940" (J C McDonald, J M Harris, G Berry, 2006) which discuss evidence that asbestos (in this paper, crocidolite) is slowly removed from the lungs. The study traced deaths from a particular cohort of workers exposed to asbestos. It found statistically significant evidence relating to an absence of mesothelioma cases at longer times from exposure, compared to those expected i.e. that the mesothelioma incidence rate did not continue to increase at older ages, indeed that there was evidence that, in the cohort under consideration it actually fell. Therefore, the results provide support to the proposition that the mesothelioma incidence rate does not continually increase with increasing time since exposure. However, there are other studies such as "Update of Potency Factors for Asbestos-Related Lung Cancer and Mesothelioma" (D. Wayne Berman and Kenny S. Crump, 2008) that suggest an increasing mesothelioma incidence rate at older ages is appropriate. There is therefore still uncertainty around both the clearance of asbestos from the lungs, and the most appropriate "track" for mesothelioma incidence rates by age.

We found that the past fit of the projection model was improved by incorporating a cut-off to the k factor. This suggests that it may have been more appropriate to have a lower increase in the mesothelioma rate by year of birth cohort in the past (and therefore assumed in the future) than assumed in the HSL model (see Section 4.4.3). This finding has been discussed with the HSE. The HSE are aware of the uncertainties, and agree that it is a potential improvement to the HSL's parameterisation of the model.

The table below details the effect of changing the half-life and $k$ factor within the model.

Table 14: Half-life and k Factor Sensitivities

| Half-life | k | All other <br> assumptions | Peak <br> year of <br> deaths | Peak <br> number <br> of deaths | Number <br> of deaths <br>  <br> post | Sum of <br> squares ${ }^{9}$ | Chi- <br> Squared <br> Deviance $^{\mathbf{1 0}}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $1,000,000$ | 2.47 | HSL 2009 | 2016 | 1,977 | 55,878 | 751.3 | 246.1 |
| $1,000,000$ | capped <br> (ca.47 <br> at 60) | HSL 2009 | 2016 | 1,965 | 54,273 | 747.0 | 151.9 |
| $1,000,000$ | 2.6 | HSL 2009 | 2017 | 2,076 | 59,123 | 879.5 | 348.9 |
| 1,000 | 2.47 | HSL 2009 | 2016 | 1,961 | 55,341 | 773.9 | 240.3 |
| 1,000 | 2.6 | HSL 2009 | 2017 | 2,059 | 58,559 | 833.0 | 334.9 |
| 34 | 3 | HSL 2009 | 2015 | 1,925 | 53,091 | 746.8 | 391.5 |
| 1,000 | 2.6 | HSE 2003/5 | 2013 | 1,849 | 43,722 | 778.0 | 282.0 |

## Exposure

The exposure in the HSL model is based on separate parameter sets regarding the exposure for:

- 20-29 year olds at each year; and
- other age bands (relative to the 20-29 year old age band).

## Exposure by year

Like " $k$ " and the half-life there is no clear-cut answer to exactly what the exposure for Great Britain should be. The exposure index used by the HSL was defined by percentages, in multiples of 10 years, from the maximum exposure year. The years in between the 10 -yearly values were determined by linear interpolation. This parameterisation produces a collective population exposure index over time. However, it is not possible to estimate this beyond the late 1970s because observations about mesothelioma to date tell us nothing about exposure more recently because of the long latency of the disease. Appeal to other forms of evidence is therefore necessary to fix the exposure profile from this point to the present day and then into the future.

The HSE previously estimated that in order for the mesothelioma projections model to predict the correct level of mesothelioma mortality in the long term (as implied by a separate exercise to predict the long term risks arising from estimated numbers and levels of exposure within different groups of the current population based on a specific dose-response model), the value of the population exposure index in year 2000 should be approximately $4.2 \%$ of the peak. These arguments are set out in the Regulatory Impact Assessment ("RIA") for the revised Control of Asbestos at Work Regulations. Though uncertain, this assessment therefore provides a single more recent point on the exposure profile to inform decisions about the profile from 1978 up to this point, and then on into the future.

[^6]The graph below details the HSE and HSL exposure indices, together with the Working Party selected exposure index, as described in Section 4.5.

Figure 30: HSE, HSL and AWP Exposure Indices by Year (for years 1925 to 2002)

The exposure index produced by the HSL has changed dramatically from that used by the HSE in 2003/5. The reason for this change is due to the optimisation process that the HSL have used to parameterise their model rather than as a result of having more data observations or using a slightly modified model. In other words, if the same optimisation techniques had been used by the HSE in 2003/5 a similar profile would have been revealed. The HSL index has multiple peaks, as opposed to the smoothed HSE single peak index.

The HSL suggest that the local peaks around 1930 and 1950 could be associated with the following events:

- The introduction of the Asbestos Industry Regulations in the UK in 1931 and the impact of the Great Depression; and
- The reduced shipyard activity, especially in naval yards, in Great Britain after the end of World War II.

Whilst it is difficult to corroborate these dramatic movements in the level of exposure to asbestos, these local peaks have little to no impact on the future estimated deaths. The key impacts of the HSL exposure index are:

- moving the peak year of exposure earlier (which reduces the total future number of deaths and the year in which deaths will peak); and
- increasing the exposure between 1976 and 1999 (which increases the total future number of deaths).

Due to the long latency periods of mesothelioma the historical deaths up to 2006 could not be used (directly) to estimate exposure levels since 1978. Therefore the HSL have chosen for their exposure index to use a straight line between the last year parameterised by the historical data (1978) and the findings from the RIA (that the exposure in 2000 is $4.2 \%$ of the peak level). From the year 2000 onwards, the HSL have assumed the exposure indices as per the 2003/5 HSE projections. There is no scientific reason for using linear interpolation between these years, nor is there any data or information that justifies a change in the assumption from the HSE 2003/5 model. That said, there was also no scientific basis for the exposure index to reach a level in 1981 and continue at that level until 2000 (as per the 2003/5 HSE projections).

We have endeavoured to use an assumption that has some rational basis and have looked at using the change in the level of imports over the period to estimate how the exposure will change from 1979 to 1999. This is represented by the dotted line in the above graph. We have discussed the selection of post-1978 exposure with the HSE. They have confirmed that their selection was not based on any other evidence and have not objected to the selection of an alternative basis.

The table below details the effect of changing the exposure index within the model.
Table 15: Exposure by Year Sensitivities

| Exposure index | All other <br> assumptions | Peak <br> year of <br> deaths | Peak <br> number of <br> deaths | Number of <br> deaths 2009 <br> \& post | Sum of <br> squares | Chi- <br> Squared <br> Deviance |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| HSL 2009 | HSL 2009 | 2016 | 1,977 | 55,878 | 751.3 | 246.1 |
| HSL 2009 using <br> import measure for <br> 1979 to 1999 | HSL 2009 | 2015 | 1,919 | 50,367 | 777.3 | 265.9 |

## Exposure by age

Age-specific exposure potential parameters, $\mathrm{W}_{\mathrm{A}}$, allow the exposure to differ by age. There are nine parameters including the baseline (set to 1) for ages between 20 and 29. Other values are set for the following ages:-

- 0 to 4 (pre-school);
- 5 to 15 (school age);
- 16 to 19 (school/work transition);
- 30 to 39, 40 to 49, 50 to 64 (work/retirement transition); and
- 65 plus (retired).

The graph below details the HSE 2003/5 and HSL 2009 age-specific exposure potential parameters.

Figure 31: HSE and HSL Age-Specific Exposure Parameters

The table below details the effect of changing the age-specific exposure assumptions within the model.

Table 16: Exposure by Age Sensitivities

| Age-specific <br> exposure | All other <br> assumptions | Peak <br> year of <br> deaths | Peak <br> number <br> of deaths | Number of <br> deaths <br>  <br> post | Sum of <br> squares | Chi- <br> Squared <br> Deviance |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| HSL 2009 | HSL 2009 | 2016 | 1,977 | 55,878 | 751.3 | 246.1 |
| HSL 2009 with zero <br> for ages 50+ | HSL 2009 | 2016 | 1,981 | 56,012 | 741.8 | 234.1 |

| HSE 2003/5 | HSE 2003/5 | 2013 | 1,849 | 43,722 | 778.0 | 282.0 |

## Population

As discussed above the HSL model uses Great British population estimates to project the number of mesothelioma deaths. There is uncertainty surrounding the following key areas of the population estimates used within the model:

- Improving longevity;
- Immigration and emigration; and
- Deaths over the age of 80 .

The HSE 2003/5 used the 2001 Great British estimated population statistics for males aged 20 to 89 from 1968 to 2050 provided by the ONS. The HSL have used the revised ONS population estimates as at mid-2006 ${ }^{11}$. These new population estimates, shown below, take into account improving longevity and more recent data on immigration and emigration.

Figure 32: ONS mid-2006 Great British Population Estimates

GB Male Population by Age Group (2006)

The Working Party have looked at the impact of removing the immigration and emigration from the model by cutting-off the population at different periods and using different ONS mortality assumptions to run-off the population. Implicit in the ONS population figures is an assumption that on balance around 15,000 males aged 45 or above will leave the UK in each future year. As mentioned in Section 4.4.3, removing this net migration assumption leads to a small increase in the projected number of mesothelioma deaths.

[^7]The table below details the effect of changing the assumed population within the model.
Table 17: Population Sensitivities

| Population | All other <br> assumptions | Peak <br> year of <br> deaths | Peak <br> number <br> of deaths | Number of <br> deaths 2009 <br> \& post | Sum of <br> squares | Chi- <br> Squared <br> Deviance |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Mid-2006 | HSL 2009 | 2016 | 1,977 | 55,878 | 751.3 | 246.1 |
| Mid-2001 | HSL 2009 | 2013 | 1,884 | 49,617 | 755.8 | 243.1 |
| Mid-2006 | HSE 2003/5 | 2015 | 1,929 | 49,155 | 770.6 | 279.3 |
| Mid-2006 with cut-off <br> at 2009 and Principal <br> mortality* | HSL 2009 | 2016 | 1,980 | 56,204 | 751.3 | 246.1 |
| Mid-2006 with cut-off <br> at 2009 and High Life <br> Expectancy* | HSL 2009 | 2017 | 1,999 | 58,008 | 751.3 | 246.1 |
| Mid-2006 with cut-off <br> at 2009 and Low Life <br> Expectancy* | HSL 2009 | 2016 | 1,964 | 54,276 | 751.3 | 246.1 |
| Mid-2006 with cut-off <br> at 2009, Principal <br> mortality and off- <br> setting mortality by +3 <br> years | HSL 2009 | 2009 | 1,859 | 50,086 | 751.3 | 246.1 |
| Mid-2001 | HSE 2003/5 | 2013 | 1,849 | 43,722 | 778.0 | 282.0 |

* Principal mortality refers to the mortality assumption underlying the ONS population projections (see Appendix G). The ONS refer to two (one higher and one lower) other potential mortality assumptions. These are differentiated by the implied life expectancies within the mortality assumption.

### 4.5. UK Asbestos Working Party Assumptions

The Working Party has selected a model structure based on that used by the HSL, but has made some changes to the selected underlying assumptions. The HSL's approach was to use optimisation processes to achieve the best possible fit to the past data. Whether or not the assumptions implied by this approach are applicable to future experience is uncertain.

We have considered alternative assumptions, some of which the HSL have not considered. These have given alternative fits to the historical data and are described above in Section 4.4. Where the parameterisations improve the fit there are still a variety of outcomes for the projected number of mesothelioma deaths - both higher and lower than those produced by the HSL model. Due to the considerable uncertainty in the selection of assumptions, the Working Party has adopted a pragmatic approach and changed some key assumptions from the HSL model to give a better fit where there was sufficient justification to do so.

A summary of the Working Party's selected model compared to the HSL 2009 is given in the table below, and the assumptions and some of the considerations made in their selection are given in the following sections.

Table 18: Comparison Working Party Model and HSL 2009

| Model | Population | Peak <br> year of <br> deaths | Peak <br> number <br> of deaths | Number of <br> deaths 2009 <br> \& post | Sum of <br> squares | Chi- <br> Squared <br> Deviance |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| AWP | Mid-2006 | 2015 | 1,912 | 48,911 | 757.9 | 157.7 |
| HSL 2009 | Mid-2006 | 2016 | 1,977 | 55,878 | 751.3 | 246.1 |

### 4.5.1. The $k$ factor

The k factor has been kept at 2.47 as per the HSL model, but has been capped for periods over 60 years from first exposure. This was discussed in Section 4.4.4. When the cap was applied, the death rates for older cohorts fitted the historical mesothelioma deaths data better. It is uncertain whether or not this assumption will be borne out for the later cohorts as they reach this duration from first exposure, but we believe this is a reasonable assumption.

The cap on $k$ limits the increase in the risk of developing mesothelioma after 60 years from first exposure. The main age-group that this affects is the 80+ group and will have the effect of reducing the projected number of deaths from this age group.

### 4.5.2. Exposure

As shown in Section 4.4.4 above, the exposure post-1978 has not been assumed to be a straight line, as the HSL assume, but has been adjusted, based on the fall in asbestos imports at this time. We have adopted an alternative exposure curve for the period from 1979 to 1999, inclusive.

Although the HSE have always used an exposure profile to 2050 and projected deaths to 2050, the 2004 Working Party estimate cut the Insurance Market projection at 2040. This was as a proxy for eliminating claims from exposure post 2004. The 2009 Working Party estimates have included exposure up to 2050, and projected deaths to 2050, giving an extra 10 years of projected deaths. The Insurance Market projections contained in this paper are intended to include all claims arising from all asbestos exposure in the UK, and hence some claims in the projections are assumed to arise from future exposures. This has therefore changed the basis of the Insurance Market projections and increased the future estimated cost. The practitioner should be aware of, and make appropriate allowance for, this fact.

### 4.5.3. Exposure by age

We believe it is more appropriate to have no exposure age adjustments post age 49, but note that this does not have a significant impact on the model fit or future projections.

### 4.5.4. Mortality

The HSL did not look at changing the mortality from that assumed in the adopted revised ONS population estimates as at mid-2006. Some investigations undertaken by the Working Party are discussed in Section 4.4.4. There is evidence that suggests that the exposed population have higher mortality than the general population. If allowance for this is made then an alternative fit of the model can be made. If we increase the mortality assumption (for example, by 5\%) then a different parameterisation of the rest of the model actually gives a better fit to the historical data, and a reduced number of projected future deaths (by about $2.5 \%$ ). This was achieved by changing the k -factor cap and the exposure profile.

[^8]However, the model currently projects deaths in males up to the age of 89. There is a possibility that deaths in males aged 90 and above could have a significant effect and so this would increase the projection of future deaths. We note that alternative fits are possible and could be investigated further. Due to the considerable uncertainty surrounding deaths at older ages, we decided not to make any mortality adjustments. We have therefore used the same population projections as in the HSL model.

### 4.5.5. Guidance to the Practitioner

The Working Party encourages the practitioner to consider the issues and sensitivities outlined in Section 4.4.4 and to select their own assumptions. The above should only be considered as guidance as to potential adjustments to the HSL assumptions that could be appropriate. The details of a working spreadsheet model of the HSL methodology containing various parameterisations including that selected by the Working Party as discussed above is given in Appendix C.

Figure 33 Comparison of Potential Population Mesothelioma Deaths Projections

### 4.6. Comparison to 2004

A comparison of the Insurance Market costs of mesothelioma deaths from the 2004 paper with our revised estimates is provided in Section 7.2.

The number of projected mesothelioma deaths has increased from the 2004 paper, partly due to the increased time horizon of the model, from 2040 to 2050, and partly to the updated population estimates (ONS 2006) used within the modelling process. The following table summarises the projected number of deaths in the current and previous models.

Table 19: Projected Mesothelioma Deaths (ages 20-89)

|  | Year of death |  |  |
| :---: | :---: | :---: | :---: |
|  | $\mathbf{2 0 0 4} \mathbf{- 2 0 0 6}$ | $\mathbf{2 0 0 7} \mathbf{- 2 0 4 0}$ | $\mathbf{2 0 4 1 - 2 0 5 0}$ |
| AWP 2004 | 5,056 | 45,212 | N/A |
| Actual | 5,087 | N/A | N/A |
| AWP 2009 | N/A | 48,945 | 3,530 |

## 5. Mesothelioma Claimants

### 5.1. Summary

An increase in mesothelioma claimant death ratios (referred to as CD Ratio - the percentage of deaths that lead to a claim for compensation) has been noted throughout the industry since the publication of the 2004 Working Party paper and was the primary driver for the reformation of the Working Party in 2007. As part of the 2008 study, the Working Party oversaw the collection of asbestos-related claim statistics across a large proportion of the UK insurance industry.

The statistics confirmed that the increase was industry-wide with male claim numbers in Great Britain (excluding claims settled at no cost, and excluding claims made against the Government) estimated to have increased from about 1,500 in 2003 to about 1,900 in 2007. The current Working Party has repeated the exercise and numbers have continued to increase, with the 2007 estimate revised (actual replacing estimated data for the second half of 2007) to 2,000 and the 2008 estimate around 2,400 .

The 2008 Working Party study concluded that increases in claimant death ratios (i.e. more sufferers claiming) was the cause rather than any change in the number of claims per claimant. Indeed there has been a fall in the number of claims per claimant as outlined in Section 3.3 and commented on in Section 5.4.3. The study further concluded that changes of this speed were unlikely to be caused by structural changes in the nature of insurance exposures but rather changes in the nature of the sufferer's 'journey'. The 2008 paper gave a detailed discussion highlighting changes and how they could affect claimant death ratios. Section 5.2 provides a recap on this discussion.

The Working Party has undertaken further work this year. Discussion with Government departments has yielded information about mesothelioma sufferer and claimant numbers that corroborates last year's conclusion. The headline male claimant death ratio for Great Britain (including Government claims) has increased from 43\% in 2003 to $63 \%$ in 2007 and an estimated $69 \%$ in 2008 . The claimant death ratio for the UK Insurance Market has increased from $\mathbf{3 6 \%}$ to $\mathbf{6 1 \%}$ over the same period. This evidence is discussed in Section 5.4.

The qualitative issues discussed in Section 5.3 have clearly had an impact on claimant death ratios. For various reasons, however, it is not possible to quantify the impact of these changes. Interpretation of recent developments and estimation of the future is therefore necessarily subjective and judgmental and will, for an individual insurer, depend on several factors including that insurer's own recent experience and reserving approach.

We make no attempt to limit the scope of judgement that each insurer will make. We have, however, set out a number of questions that each insurer should ask itself in forming a view. Section 5.5 sets out these questions and provides some further information on the potential maximum ratio.

Finally, we have developed a number of possible scenarios for claimant death ratios in the future. These have been included in the overall projections discussed in Section 5.6. Given the subjectivity of this issue these scenarios should be viewed as purely illustrative of the sensitivity of UK mesothelioma insurance cost projections to changes in the assumed claimant death ratios.

### 5.2. Recap on 2008 paper

The 2008 paper (Section 4 'Claims Life Cycle') included a discussion of the process by which an individual diagnosed with mesothelioma is then able to make a claim for compensation against an insurance company (or by extension, the Government). The section was informed by discussions with, amongst others, the NHS and claimant solicitors and provides an in-depth analysis of the process and how it has changed in recent years.

The following paragraphs (following the headings in the original paper) extract discussions of key aspects of the process and recent changes.

### 5.2.1. Medical profession

At the Primary Care Trust level mesothelioma is still such a rare condition that the majority of GPs will not have seen many cases. Mesothelioma diagnosis is unlikely to happen at this level with related symptoms being referred to a specialist in lung conditions.

There have been significant breakthroughs in medical imaging over the last decade but these appear to be having a more direct impact on other conditions. The breakthrough in mesothelioma diagnosis is in image-led biopsy, resulting in a better targetting of the tissue taken for biopsy. It is only in specialist centres where the skills are present to perform such techniques, hence the development of the National Mesothelioma Framework ("the Framework").

The Framework was published in February 2007 based on practice built up in a number of specialist centres, so that best practice can be shared nationwide. The Framework is not mandatory but the developers believe implementation should be relatively simple and largely cost neutral.

The Framework makes four key recommendations:

- Patients should be managed by a specialist multi-disciplinary team;
- Each cancer network should have a lead clinician and lead nurse;
- Local clinicians in areas with high incidence should be made more aware of the disease; and
- Patients should have a key worker for better co-ordination of treatment and information.

The Framework therefore seeks to provide, amongst other things:

- Earlier, more reliable, diagnosis;
- Better co-ordination of treatment; and
- More information to the patient.

In relation to the first of these, there is clear evidence of improvements in diagnosis rates. The paper reported an increase from $50 \%$ to $96 \%$ of mesothelioma cases confirmed before death in one specialist centre in the eight years before publication. Rates vary across the country but it is clear that the general trend will have been an increase in rates of pre-death diagnosis.

### 5.2.2. Legal profession

The paper summarised discussions held with personal-injury solicitors. The following comments may have direct relevance to changes in claimant death ratios:

- Solicitors have seen an increase in the number of people (both male and female) with mesothelioma looking to make a claim over the last five years;
- They have seen an increase in the number of living mesothelioma claimants;
- A living claimant is able to provide a witness statement which can be a key component in making a successful claim;
- There has been a slight increase in the number of cases from non-traditional sources such as nurses and teachers;
- Not all death certificates state mesothelioma as the cause of death for cases that they represent but they could not quantify this amount; and
- The ABI database (see below) has improved in that it now updates requesters in how their enquiry is proceeding, but they do not feel it has significantly increased the success rate in finding a responsible party.

### 5.2.3. Special interest bodies

Voluntary organisations and charities form an important part of the support network for individuals contracting diseases or conditions that impact normal daily life.

Mesothelioma is a rare condition and there are few organisations geared up to focus on it. A review of the National Directory of Voluntary Organisations yields no entries for charitable or voluntary bodies focussing on mesothelioma and many offering counselling services will not have come across it.

The internet on the other hand is capable of providing access to specialist information and bringing people together with a common interest. There is a wealth of information available on the web to help patients and their carers find out more about asbestos-related conditions, treatment, symptom management and support, both personal and financial.

The provision of such web-based information services has increased enormously over the last eight to ten years.

### 5.2.4. Insurance industry

Given the length of time that typically elapses, it can be a problem for the claimant or their solicitor to identify firstly the employer that exposed the claimant to asbestos and then that employer's insurers. Even if the claimant recalls their employment history in some detail, employers may have merged, ceased trading or become insolvent.

In 1999 the insurance industry, in agreement with the Government, set up a code of practice to help find a solution to this problem for claimants suffering from long-tail diseases. In support, the ABI set up a free enquiry system: the EL tracing service (often referred to as ABI tracing or ABI database).

The service originally relied on physical mail. In 2002 the process began using e-mail; mesothelioma cases were e-mailed every week. In 2005 an on-line enquiry form was created by the ABI for claimant solicitors to fill in directly. In 2007 mesothelioma enquiries were fast tracked.

The ABI has implemented further improvements in recent years to make the process easier for enquirers and to avoid unnecessary duplication for searches that had already taken place.

### 5.2.5. Legal developments

The paper discussed the development of the law on asbestos-related diseases and compensation, including Fairchild, Barker and The Compensation Act. The Compensation Act in particular has ensured that mesothelioma sufferers receive full compensation as long as one responsible party can be identified. Furthermore, in more general terms, these cases have continued to raise the profile of asbestos-related diseases and the existence of compensation in the public mind.

### 5.3. Qualitative drivers for an increase

The 2008 paper showed that there were several drivers for increases in claimant death ratios, notably:

- Improvements in pre-death diagnosis rates;
- Increasing awareness of financial compensation; and
- ABI tracing.

The Framework has had the result of improving the rate of diagnosis of mesothelioma whilst the sufferer is alive. This could have a two-fold impact. Knowing that the condition is mesothelioma whilst the sufferer is alive may result in more claims being made (for example, if a sufferer without dependents dies without knowing that he or she is suffering from mesothelioma then no claim is likely to be made). Claimant solicitors point out that claims are more likely to be successful (for example, through witness statements) if the claimant is alive.

In improving the amount of information available to sufferers, the Framework also increases the level of knowledge of financial compensation. Changes in the law and the ubiquity of the internet have also served to increase the general level of awareness of asbestos-related diseases and of the potential for financial compensation. As is the case in many areas, increased awareness of the ability to make an insurance claim can lead to an increase in claim numbers.

The claimant solicitors interviewed did not believe that ABI tracing had had much impact on claim numbers. Nevertheless, statistics compiled by an insurer represented on the Working Party demonstrated a distinct increase in enquiries to the system. The changes introduced by the ABI have made the process easier and it is likely that this has resulted in an increase in enquiries, and perhaps in claim numbers as a whole.

### 5.3.1. A comment on post death diagnosis

Claimant solicitors commented that not all death certificates state mesothelioma as the cause of death for cases that they represent. That is, not all cases of mesothelioma are recorded on death certificates.

The HSE statistics on UK mesothelioma deaths are compiled from an analysis of cause of death as recorded on death certificates. The implication is therefore that some cases of mesothelioma are outside of the HSE statistics and therefore that the universe of mesothelioma cases from which claimants may appear is wider than the HSE data and wider than the projections based on HSE data presented elsewhere in this paper. The HSE are aware of this potential and are currently investigating its veracity although they do not believe it materially distorts the HSL projections. In theory, though, it is possible that claimant death ratios could therefore exceed 100\%.

We have ignored this possibility for the following reason. The qualitative discussion of the Framework and the quantitative improvements in pre-death diagnosis rates suggest that the proportion of mesothelioma sufferers diagnosed after the death certificate is produced will be falling. By extension, this is likely to mean that the proportion of mesothelioma sufferers captured within the HSE data is rising over time and therefore that some of the recent increases in recorded deaths is due to improved diagnosis rather than true demographics.

Though the potential for improving diagnosis was allowed for in the 2003/5 HSE study, it has been excluded from the 2009 HSL study. The precise implications for future deaths is impossible to assess at this stage, but we have (for the sake of simplicity) assumed that this offsets any potential under-recording of mesothelioma-related deaths in the current data.

### 5.4. Actual experience

### 5.4.1. Industry data

The Working Party has, as in the past, overseen the collation of aggregate asbestos-related claims data across a very large proportion of the UK Insurance Industry. For mesothelioma claims, this data shows sharp increases in numbers notified, from 1,951 in 2003, 2,641 in 2007 and, provisionally, 3,052 in 2008. These figures represent $100 \%$ of the UK Insurance Market and include all claim notifications, including those settled at no cost.

### 5.4.2. IIDB

Industrial Injuries Disablement benefit ("IIDB") is a weekly allowance provided on a 'no fault' basis to people suffering from a recognised employment-related condition provided that they can demonstrate that they were employed.

The Department of Work and Pensions ("DWP") collects statistics for IIDB awards at a detailed level including age band and nature of condition. In June 2009 they shared the following statistics on IIDB awards for males with the Working Party. Numbers are rounded to the nearest ten and were qualified as 'provisional and subject to revision'.

Table 20: Number of Male Mesothelioma IIDB Benefit Awards

|  | Year |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Age Band | 2003 | 2004 | 2005 | 2006 | 2007 | to 2008 Q3 |
| 30 to 34 | 0 | 0 | 0 | 0 | 0 | 0 |
| 35 to 39 | 0 | 0 | 0 | 0 | 0 | 0 |
| 40 to 44 | 10 | 10 | 0 | 0 | 0 | 0 |
| 45 to 49 | 10 | 10 | 10 | 20 | 10 | 10 |
| 50 to 54 | 50 | 40 | 50 | 40 | 30 | 40 |
| 55 to 59 | 140 | 130 | 140 | 120 | 110 | 70 |
| 60 to 64 | 190 | 210 | 250 | 190 | 230 | 160 |
| 65 to 69 | 210 | 250 | 270 | 290 | 280 | 220 |
| 70 to 74 | 180 | 230 | 270 | 240 | 280 | 240 |
| 75 to 79 | 190 | 200 | 230 | 230 | 280 | 200 |
| 80 to 84 | 90 | 130 | 130 | 150 | 160 | 150 |
| 85 plus | 20 | 30 | 60 | 50 | 70 | 60 |
| Total | $\mathbf{1 , 0 9 0}$ | $\mathbf{1 , 2 4 0}$ | $\mathbf{1 , 4 1 0}$ | $\mathbf{1 , 3 3 0}$ | $\mathbf{1 , 4 5 0}$ | $\mathbf{1 , 1 5 0}$ |

The data shows an increase of about 30\% from 2003 to 2007 and a further $10 \%$ or so to 2008 Q3. These rates of increase are broadly consistent with the insurance industry data collected by the Working Party.

Although there will be a broad correspondence between numbers of IIDB awards and numbers of insurance claimants, there are differences:

- Because IIDB is 'no fault' there may be awards made where no employer is deemed liable for exposure and therefore there is no employers' liability claim.
- Where mesothelioma is diagnosed after death no IIDB award will have been made; however it is possible (as long as the claim is made within three years of death) that there will be an insurance-related claim.

Because of these differences we have not investigated this data further beyond noting that the change in claimant death ratios are broadly consistent with the CRU and insurance industry claim experiences.

### 5.4.3. Compensation Recovery Unit (CRU)

The CRU, part of the DWP, works with insurers, solicitors and DWP customers to recover (in the context of asbestos-related claims) amounts of social security benefits paid where a compensation payment has also been made. The CRU is responsible for recoveries in England, Scotland and Wales. A separate unit, reporting to the Department for Social Development in Northern Ireland, is responsible for collection of recoveries in Northern Ireland.

When an insurer is notified of a claim, a standard claim form must be completed within 14 days of notification and submitted to the CRU. This form is not an admission of liability and is completed for all claims, including those that may not eventually succeed.

The CRU will therefore be informed of all asbestos-related claims giving rise to compensation, whether from the insurance industry or the Government.

The following table shows data provided to the Working Party under a Freedom of Information request. Numbers are for male claimants (not claims) against the insurance industry or the Government and including a small number of public liability alongside employers' liability claimants. Columns are financial years.

Table 21: Male Mesothelioma Claimants Recorded by the CRU

|  | Year of First Claim Receipt |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Age <br> Band | $2002-$ <br> 2003 | $2003-$ <br> 2004 | $2004-$ <br> 2005 | $2005-$ <br> 2006 | $2006-$ <br> 2007 | $2007-$ <br> 2008 | $2008-$ <br> 2009 | $2009-$ <br> (part <br> year) | Total |
| $<45$ | 0 | 9 | 6 | 1 | 3 | 4 | 3 | 0 | 26 |

Note that the 2009-2010 figures represent only part of this financial year.
Similarly to the IIDB data, the rate of increase of the CRU data is broadly comparable with the insurance industry data. Given the direct correspondence between an insurer being notified of a claim and registering the claim with the CRU, however, this data should give a reliable guide to the overall industry picture.

About 10\% of registrations with the CRU are withdrawn without settlement. Note that the typical nil claim rate for mesothelioma claims is much higher, over $20 \%$. The difference is that the withdrawal of a CRU registration represents a claimant failing with any insurance claim, not just a claim against one particular insurer. In using the above data to build a picture of claimant death ratios over time, we have adjusted for this $10 \%$ withdrawal rate for the conversion from financial years to calendar years and for an assumed 1\% proportion of public liability claims.

The following graph shows the results of this work grouped by age band. The overall ratio (including Government) has increased from 43\% in 2003 to 63\% in 2007 and an estimated 69\% in 2008.

Figure 34: Claimant Ratio by Age and Year

The denominator for the ratio is the number of deaths as reported by the HSE each year. At the time of analysis the HSE had published deaths in Great Britain for 2006 but not 2007 nor 2008. HSE deaths for 2007 were estimated by grossing up mesothelioma deaths as reported by the World Health Organisation ("WHO") for $2007^{13}$ by the average factor by which the HSE had grossed up previous WHO figures. This estimate, 1,811 deaths, has proved very close to the actual HSE figure published in October 2009. For 2008, the only figure available is an ONS estimate included in a parliamentary answer reported in Hansard earlier this year ${ }^{14}$. This figure is not age banded and therefore the total estimate (1,905 deaths) and the assumed age banding in the above graph is conjectural.

### 5.5. Predicting the future

It is clear that claimant death ratios have risen and there have been structural changes in the process which will have served to increase the ratio. It has not proved possible, however, to find quantitative evidence of the impact of these changes. In some areas, such as changes across the UK in pre-death diagnosis rates, data may be collected but we have not been able to find it. In other areas, such as increasing awareness of financial compensation, there is no way of quantifying the impact.

Interpretation of recent developments and estimation of the future is therefore necessarily subjective and judgemental and will, for an individual insurer, depend on several factors including that insurer's own recent experience and reserving approach. We make no attempt to limit the scope of judgement that each insurer will make. We do, however, set out below a number of questions that each insurer should ask itself in forming a view.

These questions are:

- Have the structural changes worked their way through?
- Would rates have risen absent these changes?
- Why have rates risen faster at older ages? Does this point to some sort of maximum level?
- Could $100 \%$ of mesothelioma sufferers successfully claim? If not, what is the maximum possible level?

The Working Party has collected some further information in support of the last question. There are four known areas in which mesothelioma sufferers will not be able to make a successful employers' liability claim:

[^9]- Most members of the armed forces, as claims for mesothelioma may only be made in respect of exposure after 1987,
- People who were self-employed throughout their careers,
- People who were exposed to asbestos through domestic or background exposure.

### 5.5.1. Armed forces

Information provided to the ABI shows that the Ministry of Defense receives about 50 mesothelioma claims each year from ex-civilian personnel. The ratio of service to civilian personnel is about 2:1. On the face of it this points to about 100 sufferers per year from exservice personnel, or about $5 \%$ of the UK total. However, a proportion of these people will have been exposed during employment outside the armed forces. We put a tentative estimate for the proportion of sufferers who are unable to claim because their exposure was through the armed forces at about $1 \%$.

### 5.5.2. Self-employed

ONS statistics indicate that about $15 \%$ of the total workforce, and about $23 \%$ of the UK construction workforce, is full-time self-employed. However it is again likely that a proportion of these people will have been exposed as an employee at some time in their careers. We put a tentative estimate for the proportion of sufferers who are unable to claim because their exposure was through self-employment at about $2 \%$.

### 5.5.3. Domestic or background exposure

Prof. Peto's case study of mesothelioma sufferers ${ }^{15}$ indicated that about $15 \%$ of male cases cannot be attributed to any known occupational exposure. The study was extensive but it remains possible that it will not prove to be representative of the UK population as a whole. We put a tentative estimate for the proportion of sufferers who are unable to claim because their exposure has no known occupational cause at about $10 \%$.

Thus the total (tentative) estimate of sufferers who will not be able to make an employers' liability claim is $13 \%$. Given the large uncertainties here, it is probably reasonable to say that the figure is somewhere between $10 \%$ and $15 \%$, with a maximum possible claimant death ratio somewhere between $85 \%$ and $90 \%$.

Note that sufferers who were exposed to asbestos in the course of their employment but who can find no insurance coverage will not be able to bring a successful employers' liability claim. We have been unable to find statistics to estimate how many people this affects. This may also be judgmentally factored into the maximum claimant death ratio.

### 5.5.4. Claimant Death Ratios for the UK Insurance Market

The claimant death ratios analysed cover males in England, Scotland and Wales. Females are excluded as are males in Northern Ireland. The ratios include claimants who receive compensation from the Government. Therefore adjustments need to be made to determine claimant death ratios appropriate for the UK Insurance Market.

The proportion of claims that are paid by the Government has been estimated from data provided by the CRU. It is not possible to determine the exact proportion as not all claims can be determined as either Government or Insurance Market. Some may be a mixture of both. It has been assumed that $20 \%$ of all claimants relate to the Government. This ratio has been fairly stable over the last few years. In 2008, however, the ratio appears to be closer to $16 \%$. We have assumed that the 2008 Government percentage is a one-off and not indicative of a long-term trend. If the Government percentage were to fall relative to the Insurance Market, then the estimated costs for the Insurance Market outlined in this paper may be underestimated. This trend should be monitored in the future (see Section 10).

[^10]The CRU data records about one claim from a female for every ten claims from males. This data includes third party as well as employers' liability claims. We have concluded from the market data collection that the number of employers' liability mesothelioma claims from females has increased from around 1\% in 2003 to around $3 \%$ in 2008. The Working Party has assumed that this ratio is likely to be around $5 \%$ of the number of claims from males in the future. The current female claimant death ratio is estimated to be of the order of $20 \%$. This could imply a potential for large increases in future claims. However, Prof. Peto's study indicated that $78 \%$ of female mesothelioma sufferers could not identify any occupational asbestos exposure. The Working Party recommends (see Section 10) that the number of female claimants is monitored in the future.

The Northern Ireland HSE reports that there are about 40 mesothelioma deaths per year from males and females combined. We have not sought data on claims from the Northern Ireland CRU department so it isn't currently possible to estimate claimant death ratios. However, given that the population deaths projections and the claimant death ratios exclude Northern Ireland, it is necessary to adjust the projections for Northern Ireland claims. It is observed that considering the number of mesothelioma deaths in Northern Ireland compared to the number in Great Britain, Northern Ireland represents around 2\%, and therefore this adjustment in the estimated claim numbers has been made to allow for Northern Ireland claims.

These factors can be brought together to determine the claimant deaths ratio for the UK Insurance Market over the period 2003 to 2008, see Section 5.6. These factors can also be brought together to estimate the claims to claimant ratio. These calculations are set out below and referred to in Section 3:

Table 22: Derivation of Claims to Claimant Ratio

| Notification <br> Year | Total UK <br> Ins. Market <br> claims excl <br> Nil | Male GB <br> Claimants <br>  <br> Gov | Female <br> $\%$ of <br> Male | GB <br> Claimants | NI \% <br> of <br> GB | UK <br> Claimants | Claims to <br> Claimants <br> Ratio |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2003 | 1,540 | 547 | $0.8 \%$ | 551 | $3.1 \%$ | 568 | 2.7 |
| 2004 | 1,584 | 605 | $1.5 \%$ | 615 | $3.2 \%$ | 634 | 2.5 |
| 2005 | 1,723 | 692 | $1.1 \%$ | 700 | $2.3 \%$ | 716 | 2.4 |
| 2006 | 1,931 | 828 | $1.5 \%$ | 841 | $2.9 \%$ | 865 | 2.2 |
| 2007 | 2,066 | 915 | $2.4 \%$ | 937 | $2.0 \%$ | 956 | 2.2 |
| 2008 | 2,411 | 1,095 | $3.2 \%$ | 1,130 | $2.2 \%$ | 1,154 | 2.1 |

The total UK insurance market claims have been grossed up from the market survey data assuming the market survey covered $80 \%$ of the overall market. The $80 \%$ was used as this gave an overall claims to claimant ratio of 2.1 in 2008. This is consistent with the claims to claimant ratio derived from the claims data sampled (see Section 6). There were consistent responses from 2003 onwards (i.e. no changes in participants being able to provide data) so the $80 \%$ would be relevant for all of these years.

The fall in the claims to claimant ratio may be due, at least in part, to the Compensation Act 2006. The 2006 Act makes it clear that potentially liable employers are jointly and severally liable for the indivisible injury that is mesothelioma. Thus a claimant only has to find a single solvent liable employer and / or their insurer in order to recover $100 \%$ of their damages. Whilst technically this was the position following Fairchild in 2003 the reality was that until the Compensation Act 2006 was passed most claimant lawyers still gathered full employment details and pursued their client's claims against all known defendants. Since the passing of the 2006 Act insurers are seeing increasing evidence of claimants seeking early full damages from a single identified and solvent insurer. This then leaves that insurer to use the provisions of the Compensation Act 2006 to retrospectively seek recovery from other potential defendants to the claimant's case. This change in market behaviour could have an influence on the number of claims per claimant.

### 5.5.5. Other issues

Further considerations should be borne in mind.
First, the 2008 deaths data included in the graph in Section 5.4.3 is conjectural. A different mix of age bands in the actual deaths could change the estimated overall 2008 ratio.

The CRU data includes registrations to the end of May 2009, two months into the financial year. On the face of it, the number of registrations has actually fallen slightly. Whilst this data lacks the volume to provide credibility, it is very important for insurers to consider the firmer evidence of recent experience (including claim numbers in 2009) in forming a view of the future.

An approach that projects the same overall claimant death ratio in the future already includes some implicit allowance for increases at each age band, because of the aging of the future mesothelioma claimant population.

In creating claimant death ratios as the ratio between the number of claims and the number of deaths, there is an implicit assumption that the date of claim and date of death are fairly close. The reality is that claims are made at varying times between diagnosis and three years (statute of limitations) after death. Changes in the rate of pre-death diagnosis may have the impact of bringing some claims forward so that claims are temporarily accelerated relative to deaths. This could cause a temporary increase in the claimant death ratio that levels off after the rate of predeath diagnosis reaches a steady state.

### 5.6. Possible Future Scenarios

As Section 5.5 demonstrates, predicting future claimant death ratios is fraught with difficulty. Nevertheless, in order to illustrate the impact on the potential insurance cost of mesothelioma claims, the Working Party has put forward five scenarios as detailed in the tables below for future age banded claimant death ratios.

These scenarios may assist in the projection of future liability. They are by no means intended to cover all possible future experience. For example, a fixed claimant death ratio across all age bands together (as suggested by the original Working Party paper) is one of many possible alternatives. We make no attempt to prescribe the basis on which claimant death ratios are estimated.

Note that the scenarios outlined below are for male claimants in Great Britain including Government claims. These are then adjusted at the total level to exclude Government, allow for female claimants and claims from Northern Ireland to derive the total Insurance Market projections (see Appendix D).

The Government proportion of all claims is assumed to continue to be around $20 \%$ in the future. It is noted that this proportion appeared to be around $16 \%$ in 2008 from the data obtained from the CRU. This is assumed to be a one-off occurrence, and not reflective of a future trend.

The proportion of female claims compared to male claims is assumed to be $1 \%$ in 2003 rising to $2.4 \%$ in 2007 and $3.2 \%$ in 2008. It is then assumed to be $5 \%$ in 2009 and then to remain at this level in all future years.

The proportion of claims from Northern Ireland is assumed to have been $2.3 \%$ in the past and is assumed to continue at $2.3 \%$ in the future.

Allowing for the above adjustments implies that the claimant death ratio for the UK Insurance Market is estimated at 36\% in 2003 rising to 61\% in 2008.

## Scenario 1

Claimant death ratios by age band are fixed from 2009 onwards. The actual age banded ratios up to age 74 have been amalgamated into one average as there is no evidence of any trend in ratios up to that age. Note this scenario implies, as average sufferer ages increase, a decline in the overall claimant death ratio in the future.

Table 23: Scenario 1 Claimant Death Ratio Assumptions by Age

| Cal Yr | $0-44$ | $45-54$ | $55-59$ | $60-64$ | $65-69$ | $70-74$ | $75-79$ | $80-84$ | $85+$ |

## Scenario 4

Within ten years the claimant death ratio in each age band reaches $90 \%$ of the theoretical maximum assuming $13 \%$ of sufferers remain unable to claim. As in scenarios 2 and 3 the rate of increase in each age band decays exponentially.

Table 26: Scenario 4 Claimant Death Ratio Assumptions by Age

| Cal Yr | $0-44$ | $45-54$ | $55-59$ | $60-64$ | $65-69$ | $70-74$ | $75-79$ | $80-84$ | $85+$ |

## Scenario 5

Within five years the claimant death ratio in each age band reaches $100 \%$ of the theoretical maximum assuming 13\% of sufferers remain unable to claim. Increases are linear.

Table 27: Scenario 5 Claimant Death Ratio Assumptions by Age

| Cal Yr | $0-44$ | $45-54$ | $55-59$ | $60-64$ | $65-69$ | $70-74$ | $75-79$ | $80-84$ | $85+$ |

## 6. Mesothelioma Claimant Average Cost Per Claim

### 6.1. Summary

This section outlines how the mesothelioma average cost per claim model was constructed, and compares the approach to that adopted in 2004.

The Working Party obtained a sample of claimant costs for mesothelioma claims settling between 2001 and 2009 from 6 insurers. This data was collected through the ABI so that each insurer's data remained anonymous. This enabled claimant costs to be modelled more thoroughly than before. This has revealed two key aspects:

- The claimant costs effectively assumed in the 2004 Working Party projections were lower than the true claimant costs; and
- There is a larger age-related component within the claimant costs than was previously assumed.

These two factors have off-setting impacts on the overall Insurance Market projections compared to those made in 2004.

The model developed is fairly complex, but it has been designed such that it is fairly simple to use alternative assumptions. The model is available, complete with documentation, on the Actuarial Profession's website (see Appendix C for details). It should be noted that this model relies on output from other models outlined in this paper.

Whilst the model will give a reasonable estimate of the total claimant costs, it could over estimate the insurance cost due to the impact of FSCS payments. This is discussed further in Section 6.4.3.

### 6.2. Comparison of 2004 and 2009 Working Party Approaches

### 6.2.1. 2004 Approach

The 2004 Working Party derived assumptions for the average cost of each mesothelioma claim using a model comprising of two main components:

- A 'lost years' or age-related component comprising a loss of earnings element up to age 65 and a loss of pension element from age 65 to death; and
- A 'fixed' component to allow for all other indemnity and legal costs.

The first of these was calculated as the product of a multiplicand (representing the wage/salary and pension) and a suitable factor derived from the Ogden Tables, which varied by age and allowed for the claimant's life expectancy based on suitable mortality and investment return assumptions.

However, a review by the Working Party led to a conclusion in the 2008 update paper that further elements of the total claims cost were in fact age dependent. In addition, the review also highlighted that differences existed in the size of some of the components of the total claim cost depending on whether the claimant was living or deceased at the time of settlement. These observations have led the Working Party to revise its approach for estimating the average cost of mesothelioma claims as described in the following paragraphs.

### 6.2.2. 2009 Approach

In order to obtain greater insight into the make up of the overall mesothelioma average claims cost, the Working Party decided to gather sample data from a number of major insurers. This sample contains a breakdown of costs between the different heads of damage to ascertain whether each of these was age dependent and also whether they differed depending on whether the claimant was living or deceased at the time of settlement.

Following discussions with various claims handlers, we decided to separate mesothelioma claim costs into the following component heads of damage, which are described in more detail in Section 6.3.2:

- General Damages;
- Special Damages;
- CRU/PWCA Amounts;
- Bereavement Award;
- Funeral Expenses;
- Costs of Care;
- Miscellaneous Expenses;
- Other; and
- Legal Expenses.

A model was then constructed to project each of these heads of damage in turn by year of settlement and the age of the claimant at settlement, separately for living and deceased claimants (if applicable). Allowance was also made for the predominant driver of inflation separately for each head of damage. These amounts were then aggregated to produce a total average cost for mesothelioma claims in each future settlement year for each different age at settlement, separately for living and deceased claimants.

Our analysis of the sample data and the selection of the different assumptions for each head of damage is discussed in the Section 6.3.

### 6.3. Data Sample

### 6.3.1. Background

The sample comprised the claimant costs of approximately 350 mesothelioma claims settling between 2001 and 2009 from 6 insurers. The claim amounts represented the 100\% claim value (i.e. the indemnity amount that the claimant receives) and not the respective insurer's share of the cost. The sample data did not include legal expenses/costs that would normally be allocated to the claim in addition to the indemnity costs. Allowance was subsequently made in the model for this element of the total claims cost. This is discussed further below.

The claims sample was made up of a mixture of mesothelioma claims from England, Wales and Scotland and hence should provide a reasonable estimate of the average settlement costs for mesothelioma claims in Great Britain. Whilst there are differences in the compensation amounts between Scotland and the rest of Great Britain due to differences in the respective legal systems, this differential was not measured as part of this exercise.

The data collected did not contain a specific indicator as to whether the claimant was living or deceased at the time of settlement. We decided that the best proxy available for this was to identify those claims with a non-zero bereavement award and to classify these claimants as deceased on the basis that we would not expect living claimants, in general, to receive a bereavement award. The data was collected in anonymously so that data from an individual insurer could not be identified and, further, no individual could be identified from the sample data collected.

### 6.3.2. Claim Cost Components within Data Sample

The following paragraphs provide a brief explanation of the main claim cost components (i.e. separate heads of damage) that make up the total cost of a typical mesothelioma claim. In addition, we have included comments based on the a priori views of various experienced claims handlers as to the factors that will potentially affect the size of the respective claim cost components.

### 6.3.2.1 General Damages

This element of the claims cost represents the amount awarded to compensate for any pain, suffering and loss of amenity caused. It is usually a fixed amount as set out in the Judicial Studies Board ("JSB") Guidelines. The current version (version 9 published in 2008) suggests a lower limit of $£ 52,500$ and a higher limit of $£ 81,500$, although in exceptional circumstances an award outside this range may be granted.

The amount will vary according to the individual circumstances of the case, with a longer period of suffering typically leading to a higher compensation amount. In addition, it is usually thought that a younger claimant would be more likely to achieve compensation at the higher end of the scale, although claims handlers do not believe that this should be a strong influence. The claims handlers believe that the majority of cases should be settled at the lower end of the range. The claim handlers do not expect any difference between the amounts paid to living and deceased claimants.

The JSB Guidelines state that compensation levels should increase in line with the Retail Price Index (RPI). This can be cross-checked against past editions of the JSB Guidelines. A summary of the lower, mid and upper points from previous versions of the JSB Guidelines is provided in the following table:

Table 28: General Damages Award Sizes from JSB Guidelines

| JSB Guidelines \# | Year | Low | Mid | High |
| :---: | :---: | :---: | :---: | :---: |
| 5 | $2000 / 1$ | 40,000 | 45,000 | 50,000 |
| 6 | $2002 / 3$ | 40,000 | 50,000 | 60,000 |
| 7 | $2004 / 5$ | 45,000 | 57,500 | 70,000 |
| 8 | $2006 / 7$ | 47,850 | 61,075 | 74,300 |
| 9 | $2008 / 9$ | 52,500 | 67,000 | 81,500 |

Over the full period the inflation rate has been around $5 \%$, and more towards $4 \%$ over the past 4 years. Note that the inflation rate has also been higher for the upper band compared to the lower band. This is considered by the claims handlers to be a correction that was specifically made and hence therefore not necessarily to be repeated in the future. Based upon this observed experience, and in particular, the difference over the last few years with the Retail Price Index, we have used an assumption in respect of future inflation for the general damages claim element of $2 \%$ greater than the assumed underlying RPI.

### 6.3.2.2 Special Damages

This element of the claims cost represents the amount awarded to compensate the claimant for any future loss of earnings and any future loss of pension entitlement. It is generally calculated as the product of a 'multiplicand' (the amount being compensated for i.e. salary and/or pension) and a 'multiplier' (the equivalent of an Ogden Factor to allow for expected mortality and the time value of money). The amount payable will typically vary between deceased and living claimants as discussed below.

For deceased claimants, where there are dependants, the first step in calculating the size of the claim is to determine the income and/or value of the services that the deceased would have provided. These could have included some or all of the following:

- Wages - the deceased could have been expected to be employed to say age 60 to 70 ;
- Pensions - need to consider both state and occupational;
- Benefits - the claimant might have been in receipt of state benefits and he would have expected these to have continued had he not contracted mesothelioma; and
- Services - such as DIY and gardening. These tend to be paid at a fixed amount per annum up to a certain age, say 75 .

The first three items would normally be summed together and the multiplicand calculated as:
$2 / 3$ * (total claimant income + independent family income) - independent family income
It is likely that the income will be staged by age (e.g. 55 to $65,65+$ ) so that the appropriate multiplier is used. Services will generally be included as a separate item. The factor of $2 / 3$ is usually increased to $3 / 4$ if children are involved.

In cases where there are no dependants, no claim will typically arise.
For living claimants, the claim amount relates to the claimant's 'lost years' of earnings. The income to be replaced here is the surplus of the claimant's expected earnings over the amounts the claimant would have been expected to spend on living expenses (e.g. food and bills). This will vary depending on the different levels of income (e.g. wages, pension etc.) The multiplicand is then usually estimated as $50 \%$ of the claimant's total income (i.e. that expenses are typically assumed to be half the sufferer's income).

It can be seen that if the independent family income is greater than half of the claimant's total income, then the multiplicand for a deceased claimant will be less than the multiplicand for a living claimant with the same total income. The converse is also true, and claims handlers believe that this scenario will usually be the norm. Therefore, claims handlers believe that there may be a slight differential between living (lower cost) and deceased claimants (higher cost).

In general, the multiplicand should increase in line with wage inflation with a slight reduction due to the element relating to the allowance for services, which tends not to increase at the same rate and in addition is not usually paid beyond a certain age. There has also recently been an increase in the propensity to claim occupational pensions, and if this trend were to continue in the future, it would lead to inflationary increases above wage inflation.

The multiplier for both deceased and living claimants is usually calculated based on the Ogden Tables. Adjustments will often be made for the claimant's state of health relative to the norm and other factors such as whether the claimant smoked. According to claims handlers the adjustments usually made range from a reduction of two years to an increase of up to five or six years in the claimant's age. This is consistent with the Working Party's findings based on the sample data, that a 5 year increase to the claimant's age is the best fit as described below. The multiplier will be an amalgamation of a number of separate multipliers (for example, one applying to the wage component and a separate one applying to the pension component). Since Ogden factors vary with age, so will this component of the total claim cost.

### 6.3.2.3 CRU / PWCA Amounts

The CRU element of the claims cost relates to state benefits previously paid to the claimant, which are subsequently recovered from the insurer(s). In the sample data, the CRU amount related to the amount that has not been off-set against any other elements of the claim cost and therefore needs to be paid directly to the CRU, thus forming part of the overall claim cost to the insurer. The sample data has been constructed such that an individual head of damage is recorded gross of the CRU off-set and hence the CRU element of the claims cost is only the amount that could not be off-set against a separate head of damage.

This may be clarified by the following example:

Assume that state supported care benefits received by the claimant amounted to $£ 2,500$ and that they can be fully off-set against the amount payable by the insurer. Assume further that the claim costs in relation to the cost of care were $£ 7,500$. In the sample data this would be recorded as $£ 7,500$ under the cost of care head of damage and zero in the CRU element. In reality, the claimant receives $£ 5,000$ from the insurer(s) ( $£ 7,500$ off-set by the $£ 2,500$ ) and $£ 2,500$ is provided to the CRU. If the amount could not be off-set then the total amount paid would now be $£ 10,000$, with the insurer paying the claimant $£ 7,500$ and the $C R U £ 2,500$. These amounts would then be recorded as such in the sample data.

The latter will be the case for the payments made in line with the Pneumoconiosis etc. (Workers' Compensation) Act 1979 (PWCA). Prior to October 2008, the PWCA amount was fully off-set and not recovered by the CRU. However, subsequently, whilst the benefit can still be off-set, it will also be recovered from the insurer by the CRU. Hence the overall claims cost will increase. The PWCA amounts recorded in the sample data were the relevant amounts for information only.

The following are relevant benefits that fall under the remit of the CRU:

- IIDB (Industrial Injury Disability Benefit) - cannot be off-set;
- AA (Attendance Allowance) - can be off-set;
- CAA (Constant Attendance Allowance)- can be off-set;
- DLAC (Disability living allowance care component) - can be off-set (if relevant); and
- DLAM (Disability living allowance mobility component) - can be off-set (if relevant); and
- PWCA (Pneumoconiosis etc. (Workers Compensation) Act 1979 - Post October 2008 can be offset.

These amounts are expected to increase in line with RPI based on the JSB Guidelines. The claims handlers do not expect that there should be any difference between living and deceased claimants or variation according to the age of the claimant, except that younger claimants can claim for benefits linked to loss of income and older claimants may not be aware of all the awards that can be claimed for. It is therefore possible that some age differential will be seen.

### 6.3.2.4 Bereavement Award

This element of the claims cost is paid in situations when the claimant is deceased at the time the claim is settled and where there is also a surviving spouse (or civil spouse).

The amount payable is fixed depending solely on the date of death and is increased periodically by the Ministry of Justice. Historical amounts awarded are as follows:

- $£ 3,500$ from 1982 to 1989
- $£ 7,500$ from 1990 to April 2002
- $£ 10,000$ from April 2002 to December 2007
- $£ 11,800$ from 1st January 2008

As the Ministry of Justice are responsible for determining any increases to the award, it is likely to increase in line with RPI as per the JSB guidelines. This is evident from the above awards: The latest revision saw an 18\% increase after 6 years at the previous level, which equates to under a 3\% per annum increase over that period.

By definition some deceased claimants will not receive this award (as they have no spouse). The claim handlers believe the number of claimants in this category is fairly low. They estimate around $20 \%$ of deceased claimants fall into this category. However, notwithstanding this, we consider that the existence or otherwise of a bereavement award to be the most reliable indicator in the sample data as to whether a claimant was deceased or living at the time the claim is settled. A bereavement award should not, in theory, be paid to living claimants.

### 6.3.2.5 Funeral Expenses

This element of the claims cost is intended to cover the costs associated with a funeral.
According to claims handlers these are currently likely to be in the region of $£ 2,600$ to $£ 3,000$ in total per claimant. These have seen increases in recent years as funeral costs have escalated, but this is not thought likely to continue indefinitely.

These costs are most likely to increase in the future in line with a mixture of RPI and wage inflation, with the price-related element potentially being specific.

An allowance for funeral costs is often incorporated into settlement amounts, regardless of whether the claimant is living or deceased at the time of settlement. Therefore the number of claims including a component for funeral expenses is expected to exceed the number of deceased claimants. Consequently, it is not regarded as a particularly reliable indicator of whether a claimant is deceased at the time of settlement.

It is unlikely that there will be a differential in the funeral costs by age. Funeral costs have been assumed to differ between living and deceased claimants as they will not be incorporated in all cases for living claimants.

### 6.3.2.6 Care Costs

This element of the claims cost relates to the amount of care required by the claimant, which is typically heavily weighted towards the last few months of the claimant's life. According to claims handlers it is currently typically around $£ 7,500$ to $£ 10,000$ per claimant. It is usually calculated by multiplying a rate per hour by the number of hours involved. In addition, there can also be an additional amount paid if any special care equipment is needed by the claimant. There is potential for the care costs for the claimant to increase beyond the average rate of inflation in the future.

These costs are likely to increase in line with the hourly salaries of care assistants and so should be linked to (care) wage inflation. Furthermore, the size of this part of any claim could increase in the future if the longevity of claimants post diagnosis increases due to improved medical procedures. In general, these costs should not vary with age and deceased and living claimants should receive roughly the same amount.

### 6.3.2.7 Miscellaneous Expenses

This element of the claims cost covers the costs incurred in relation to travel, medication, aids etc. Whilst these amounts could vary by age, this was not shown to be the case within the sample data, and hence no differential has been assumed. These amounts are also unlikely to vary between living and deceased claimants. They are most likely to increase in line with RPI.

### 6.3.2.8 Other

This element of the claims cost will relate to interest on out-of-pocket expenditure prior to the settlement of the claim along with interest on the amount of general damages awarded from date of issue of proceedings until the date of settlement. In the sample data it could also include any differences due to specific negotiations for certain cases, for example, if a higher or lower amount is agreed than is ordinarily paid for one of the individual heads of damage but is not reflected in the appropriate head of damage.

It will also include an allowance for previous loss of income, such as wages lost in the period between the claimant having to give up work at the onset of the illness and the date of the settlement or death, if earlier. This portion of the costs is therefore likely to increase in line with wage inflation. The amounts are assumed to be the same for living and deceased claimants, with no differential by age.

### 6.3.2.9 Legal Expenses

The sample data collected did not include an allowance for legal costs. A separate piece of analysis was carried by the Working Party to derive a suitable age dependent relationship to an estimate of the total average legal cost for the Insurance Market in relation to mesothelioma claims. No differential between living and deceased claimants was incorporated and it was assumed that amounts would increase in line with wage inflation.

### 6.3.2.10 Ogden Factor Analysis

Based on the sample data we were able to infer the average adjustment applied to the standard Ogden Factors to allow for the different mortality of the average mesothelioma sufferer compared to the population at large.

From the sample data we calculated the average Ogden Factor used in the claim payments for each age at settlement. We then compared these with the standard $6^{\text {th }}$ Edition Ogden Factors for life (males) and used least squares regression to identify the most appropriate age adjustment to make to reflect the life expectancy of the claimants. This analysis indicated that an increase of 5 years to the age should be used - i.e. for a claimant aged 70 the standard factor for age 75 should be employed as the multiplier in the calculation of special damages element of the claims cost.

### 6.3.3. Analysis of Data Sample

The following table shows the average levels of compensation in relation to each of the heads of damage as observed in the data sample, along with the average age at settlement and the average implied Ogden Factor:

Table 29: Mesothelioma Claims Cost by Head of Damage

| Averages From Sample Data | Average <br> Amount (£) | Proportion <br> of Total Cost |
| :--- | :---: | :---: |
| Average Age at Settlement | 69 |  |
| Average Ogden Multiplier | 10 |  |
| Special Damages | 65,308 | $42 \%$ |
| PSLA (pain suffering and loss of amenity) | 57,257 | $37 \%$ |
| CRU | 3,525 | $2 \%$ |
| PWCA | 6,574 | $4 \%$ |
| Bereavement Award | 5,536 | $4 \%$ |
| Funeral Expenses | 1,901 | $1 \%$ |
| Care Cost | 7,708 | $5 \%$ |
| Miscellaneous Expenses | 4,765 | $3 \%$ |
| Other | 1,507 | $1 \%$ |
| Total | $\mathbf{1 5 4 , 0 8 1}$ | $\mathbf{1 0 0 \%}$ |

From this, it is immediately apparent which components are the main drivers in the total compensation amounts paid by insurers. The special damages element which comprises the product of the Ogden Factor and the loss of income multiplicand and the general damages award relating to pain, suffering and loss of amenity make up the vast majority (almost 80\%) of the total cost and consequently will be the areas of greatest impact in the Insurance Market projections.

The data relating to each of the heads of damage discussed above was then considered separately to ascertain whether there were any apparent material age-based relationships. This was completed by fitting two straight lines through the data points, one using all data points, the other using the average values for each age at settlement. This investigation was performed separately for living and deceased claimants, as well as for all claimants combined.

Following this analysis, the results were considered along with the views from claims handlers, to decide on which elements of the claims cost should be considered as age dependent, and for which elements of the claims cost there should be a differential between living and deceased claimants.

Decisions were also taken as to the most relevant inflation index to apply, between RPI or wage inflation, with a specific addition to RPI to reflect court award inflation. For simplicity we decided that each head of damage should have only one category of inflation applying to it.

The table below shows the relevant projection assumptions applied for each of the different heads of damage.

It can be seen from the table below that some variances exist between the assumptions we employed and the initial views of claims handlers, namely:

- General Damages inflation - 'Court' rate i.e. RPI +2\% used as opposed to RPI as outlined in the JSB Guidelines reflecting the differentials observed in the past JSB guidelines.
- CRU - assumed to be age dependant and to differ between living and deceased claimants as observed in the sample data.
- Funeral costs - assumed to differ between living and deceased claimants as they will not be incorporated in all cases for living claimants.

Table 30: Summary of Mesothelioma Average Cost Assumptions

| Head of Damage | Age Related? | Inflation Type | Live I <br> Deceased <br> Differential? |
| :--- | :---: | :---: | :---: |
| General Damages <br> (Pain / suffering / loss of amenity) | Yes | Court <br> (RPI + 2\%) | No |
| Special Damages (loss of future income) | Yes | Wage | Yes |
| PWCA | No | RPI | No |
| CRU | Yes | RPI | Yes |
| Bereavement Award | No | RPI | Yes |
| Funeral Expenses | No | RPI | Yes |
| Care Costs | No | Wage | No |
| Miscellaneous Expenses | No | RPI | No |
| Other | No | Wage | No |
| Legal Expenses | Yes | Wage | No |

Finally the sample data was used to select a base value (which we chose to be the claims cost for a 68 year old settling a claim in 2007) for each of the different heads of damage, differentiating between living and deceased claimants, as appropriate.

Different assumptions within the model were used for RPI, wage and court inflation.. We have based the model on an RPI assumption, assuming wage inflation is $1.5 \%$ above this level. Our central RPI assumption is $2.5 \%$ implying wage inflation of $4 \%$ and court inflation (for general damages) of $4.5 \%$. The practitioner is encouraged to choose the base rate of inflation and wage and court differentials that they consider most appropriate.

### 6.4. Average Cost per Claim Projection

### 6.4.1. Projection

For each of the different heads of damage, we applied the assumed age relationships and inflation rates to the base level, to derive matrices of the expected claims costs by the age of the claimant at settlement and the settlement year. This can be done separately for living and deceased claimants if appropriate, though it was assumed in our projections that the mix between living and deceased claimants remained constant in the future at the level currently estimated. These matrices were then combined with the projected future mesothelioma insurance claim numbers to derive an expected future cost of mesothelioma claims to the Insurance Market. These results are detailed in Section 7.

### 6.4.2. Sense Checks

As a check the modelled settled claimant costs in the period 2007 to 2009 were compared to the actual claimant costs in the data sample. This check was performed by entering in the model the number of claims by age band, differentiating between living and deceased claimants, in the sample data, and comparing the derived modelled average claim amounts to the actual sample average claim amounts. The results are shown below.

Table 31: Mesothelioma Sample v Model Averages Cost Amounts

| Settlement <br> Year | Sample Data Average <br> (excl. legal costs) (£) | Modelled Data Average <br> (excl. legal costs) ( $£$ ) | \% Difference |
| :---: | :---: | :---: | :---: |
| 2007 | 151,614 | 149,163 | 1.6 |
| 2008 | 144,071 | 145,352 | 0.2 |
| 2009 | 146,722 | 146,364 | $(0.2)$ |

There are small differences, which may be explained by the banding of ages within the model. The number of claims within the sample for each settlement year for each age band split by living or deceased claimant will be small. It is therefore likely that the average age assumed for each age band is not equal to the actual average for the small number of claims, and hence small differences can arise. It is also noted that the sample average in 2007 is distorted by one particularly large claim.

Further, the claims data can be cross-referenced to the survey data collected (see Section 3). The average settled claim amount for a non-nil insurance claim settled in 2008 is around $£ 80,000$. It is assumed that on average these claims would have been notified in 2006 when it is estimated that the claims to claimant ratio was 2.2. This implies that the claimant cost underlying the data collection is $£ 176,000$. The average legal spend on claims settled at this time is thought to be around $£ 31,000$. Hence the total claimant cost excluding legal expenses implied by the data collection exercise is $£ 145,000$. This is consistent with the sample and modelled averages.

Overall it is believed that the parameterisation of the model is reasonable, and hence the future projected claims costs have been used to derive the Insurance Market estimates outlined in Section 7.

### 6.4.3. Potential Prudence in the Average Cost Assumptions

It should be noted that the average cost per claimant analysis described above considers the breakdown of the sample data across the heads of damage and represents the total compensation paid to the claimants. The summary data described in Section 3 represents the individual submissions received from the participating insurers and as such may not cover those elements not picked up by insurers e.g. payments made by the FSCS on behalf of insolvent insurers or payments made by the Government, though the analysis in Section 6.4.2 suggests that this impact is likely to be small.

The average number of claims per claimant assumed to derive the total average claimant costs by settlement year from the survey data does not include FSCS or the Government as claims parties. However, the total average claimant cost as per the average claim model has been used to estimate the total Insurance Market impact and hence there is the potential for the total Insurance Market impact to be slightly over estimated.

## 7. Mesothelioma Insurance Market Costs

### 7.1. Range of Results

To arrive at the estimated number of mesothelioma claimants we combined the population deaths model described in Section 4 with the future claimant death ratio (CD ratio) scenarios described in Section 5. This provided an estimate of the number of claimants bringing insurance claims in each future year. The output from this model was produced by age band and was then fed into the average cost per claim model described in Section 6. Age specific average costs were applied to the number of claimants within that model to determine the Insurance Market costs in each future year.

The CD ratios set out in Section 5.6 and used within the process described above estimate the number of claimants bringing claims to both the Government and the Insurance Market. The assumed proportion of these claims that relate to the Government has been used to adjust the model outputs. A factor of $20 \%$ has been used as the Government proportion in the future based on historical proportions according to the CRU data.

The population deaths model provides an estimate for male mesothelioma sufferers only. The CD ratio scenarios have been determined on this basis as well and, as a result, the outputs of the model are for future male claimants only. The survey data collection suggests that female claims as a proportion of male claims have risen over the last few years to around 3\%. This was assumed to be $5 \%$ in the future, and therefore we have increased the results by this amount. This produced estimates of future mesothelioma insurance claims from both male and female claimants for Great Britain.

In order to gross up to the UK, an estimate has been included for Northern Ireland. It was assumed that Northern Ireland represented $2.3 \%$ of Great Britain claims. Therefore we have increased the results by this amount. These adjustments are included in the results set out in this Section and within the appendices.

As described earlier there is significant uncertainty surrounding the future emergence of mesothelioma insurance claims in the UK. Much of this uncertainty arises from the assumptions made about the future population deaths and the CD ratio that is then overlaid to estimate the future number of claimants. A range of central estimates is provided in the table below. These use the Working Party adjusted HSL model for the population deaths. Three central CD ratio scenarios are used to arrive at future claimant numbers.

These scenarios are outlined in Section 5:

- CD Scenario 2 - Ratios across all age bands increase for ten years. The rate of increase each year is a set (decaying) proportion of the increase in the previous year.
- CD Scenario 3 - Ratios across all age bands increase for fifty years. The rate of increase each year is a set (decaying) proportion of the increase in the previous year.
- CD Scenario 4-Within ten years the claimant death ratio in each age band reaches $90 \%$ of the theoretical maximum assuming $13 \%$ of sufferers remain unable to claim. As in scenarios 2 and 3 the rate of increase in each age band decays exponentially.

Table 32: Mesothelioma Projection Results

| Projection Summary (£m) | RPI Inflation |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| CD <br> Scenario | Total <br> Projected <br> Claims | $\mathbf{1 . 5 \%}$ | $\mathbf{2 . 5 \%}$ | $\mathbf{3 . 5 \%}$ |
| Scenario 2 | 59,673 | 7,862 | 9,699 | 12,081 |
| Scenario 3 | 61,707 | 8,165 | 10,104 | 12,623 |
| Scenario 4 | 64,787 | 8,477 | 10,468 | 13,049 |

These figures represent the outcome of alternative reasonable assumption sets that may each be considered as central estimates. They are not intended to represent "optimistic" or "pessimistic" scenarios nor indicate a range of reasonable outcomes.

The above results have been derived using the Working Party adjusted HSL model for the population deaths. Different results will be obtained if alternative population death projection models are used. The following two tables summarise the results obtained when the latency and alternative simple birth cohort models are used.

Table 33: Mesothelioma Projection Results (Latency Model)

| Projection Summary (£m) |  | RPI Inflation |  |  |
| :---: | :---: | :---: | :---: | :---: |
| CD <br> Scenario | Total <br> Projected <br> Claims | $\mathbf{1 . 5 \%}$ | $\mathbf{2 . 5 \%}$ | $\mathbf{3 . 5 \%}$ |
| Scenario 2 | 44,662 | 5,303 | 6,227 | 7,347 |
| Scenario 3 | 45,681 | 5,436 | 6,396 | 7,564 |
| Scenario 4 | 48,272 | 5,691 | 6,689 | 7,901 |

Table 34: Mesothelioma Projection Results (Alternative Simple Birth Cohort Model)

| Projection Summary (£m) |  | RPI Inflation |  |  |
| :---: | :---: | :---: | :---: | :---: |
| CD <br> Scenario | Total <br> Projected <br> Claims | $\mathbf{1 . 5 \%}$ | $\mathbf{2 . 5 \%}$ | $\mathbf{3 . 5 \%}$ |
| Scenario 2 | 79,148 | 10,130 | 12,501 | 15,548 |
| Scenario 3 | 82,406 | 10,596 | 13,120 | 16,372 |
| Scenario 4 | 86,700 | 11,036 | 13,637 | 16,980 |

Overall, we have run 75 scenarios comprising 5 different population models described in Section 4, 5 different CD ratio scenarios described in Section 5 and 3 different assumptions for inflation equivalent to future RPI of $1.5 \%, 2.5 \%$ and $3.5 \%$. These give a broad range of outcomes with the lowest future Insurance Market cost estimated at $£ 4.8 \mathrm{bn}$ and the highest at $£ 30.0$ bn. The full set of scenario outputs is included in Appendix D.

The results of these 75 scenarios are for illustrative purposes only. Care should be taken when interpreting the scenario results. They include model selections and assumptions sets which, whilst possible, would not be considered appropriate as a best estimate. The scenario results are not intended to define a set of possible outcomes or to indicate any percentiles that may be used in a stochastic range of results. Possible outcomes may fall outside of the range of results displayed. The quantification of the distribution of possible results has not been considered within this paper.

### 7.2. Comparison to 2004 Working Party Results

The 2004 Working Party mid estimate for mesothelioma Insurance Market claims notified between 2009 and 2040 was $£ 4.0$ bn. The 2009 results are more than double this for the same period. The vast majority of the increase has arisen due to an increase in the CD ratio over the past 5 years.

The table below gives an approximate analysis of change. This is shown for each of the CD ratio scenarios shown in the table above, based on a future RPI inflation rate of 2.5\%. The most material change is in the CD ratio, both observed in the past and assumed in the future. This accounts for an increase of around $74 \%$ to $89 \%$ in the estimated Insurance Market cost, depending on the CD ratio scenario selected for the 2009 projections. The change in the projection of the population deaths increases the estimated Insurance Market cost by around $16 \%$. Including claims notified between 2041 and 2050 results in an increase in the estimated Insurance Market costs of around $20 \%$. However, this amount is expected to be paid more than 30 years into the future so on a discounted basis the increase is much less material. The remainder of the change in the estimate is accounted for by the change in the average cost per claim methodology.

Table 35: Mesothelioma Analysis of Change Between 2004 and 2009 Projections

| Insurance claim notifications (Incurred value 100\% market) £m |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

|  | Increase (amount) |  | -599 | -575 | -699 |
|  | Total post change |  | 8,131 | 8,415 | 8,774 |
| Claims notified 2041-2050 |  |  | 2009-2050 | 2009-2050 | 2009-2050 |
|  | Increase (\%) |  | 19\% | 20\% | 19\% |
|  | Increase (amount) |  | 1,569 | 1,688 | 1,694 |
|  | Total post change |  | 9,699 | 10,104 | 10,468 |

## 8. Non Mesothelioma Insurance Cost

### 8.1. Lung Cancer

### 8.1.1. Summary

The projection of lung cancer claims is subject to considerable uncertainty. Only a tiny fraction of all lung cancer deaths in the UK results in an asbestos-related claim (a few hundred claims compared with tens of thousands of total deaths) and it is highly uncertain how this proportion could potentially change under different circumstances.

It seems likely that the biggest influences on lung cancer claims are smoking rates and the propensity to claim. We have attempted to project claim numbers using a pragmatic methodology based on these underlying drivers.

The following table demonstrates a cross-section of such outcomes, where Scenarios 1 to 3 all represent credible forecasts for how future claim numbers and total claim costs might develop:

Table 36: Lung Cancer Projection Results

| Projection Summary (£m) | Inflation Assumption |  |  |  |
| :---: | ---: | :---: | :---: | :---: |
| Scenario | Total <br> Projected <br> Claims | $\mathbf{1 \%}$ | $\mathbf{3 \%}$ | $5 \%$ |
| Scenario 1 | 3,799 | 171 | 201 | 238 |
| Scenario 2 | 8,378 | 395 | 512 | 679 |
| Scenario 3 | 19,504 | 952 | 1,332 | 1,913 |

These forecasts are materially higher than the forecasts made by the 2004 Working Party for the same time period, which ranged from $£ 17 \mathrm{~m}$ to $£ 706 \mathrm{~m}$. A major factor in the change in the forecast is the availability in this study of better quality lung cancer claim data than was available in 2004; the actual data experience is set out in more detail in Section 3.4.

### 8.1.2. Background Investigations

It has long been known that lung cancer is particularly associated with smoking. There is also evidence that it is associated with asbestos exposure. It is this latter association that leads to asbestos-related insurance claims.

It is difficult to separate the impact due to smoking (and other contributory effects) from the impact due to asbestos exposure. Legally, where a sufferer has also smoked, they are deemed to have contributory negligence and so obtain a reduced award.

In the projection of future asbestos-related lung cancer claims, however, we need to investigate the relative degrees of impact from smoking and asbestos exposure. The 2004 Working Party paper (page 27) quoted the following expected relative impacts of contracting lung cancer from smoking and asbestos exposure:

## Type of Person Risk of Lung Cancer

Non-smoker / No Asbestos Exposure 1
Non-smoker / Asbestos Exposure 5
Smoker / No Asbestos Exposure 11
Smoker / Asbestos Exposure 52

On the face of it, this indicates that smoking by itself has twice the impact as asbestos exposure by itself and that the combination of the two is particularly severe, being ten times as bad as pure asbestos exposure and five times as bad as purely smoking.

If we believe these relativities, the implication is that it is smoking trends that drive lung cancer cases rather than asbestos exposure. Even when talking about asbestos-related lung cancer insurance claims, it is still the underlying smoking patterns that are the biggest driver of claims, since all other factors being even, cases without smokers would form only about $8.8 \%$ of all asbestos-related lung cancers.

It should be noted, however, that whilst the above figures are in common use, they do not necessarily form the true underlying picture. In recent years, for example, the impact of passive smoking has begun to be understood and it is hard to separate this from the "non-smoker with asbestos exposure" category. As incidences of smoking reduce and smoking is eliminated in public places, we might expect that the apparent "non-smoker / asbestos exposure" relativity to reduce.

Furthermore, according to Cancer Research UK, "The second most important risk factor for lung cancer is exposure to radon gas. Radon is a naturally occurring radioactive gas that can seep out of the soil."16 It is unclear how the quoted relativities were arrived at and to what extent they allow for varying demographic exposures to factors such as radon.

## Evidence For Relative Importance of Asbestos And Smoking

Although we refer to "lung cancer" as a single disease, in truth there are a number of different diseases grouped together under that broad banner. It may be that some of these are more affected by smoking and/or asbestos exposure than others. In fact, a 1999 Finnish study entitled "Lung Cancer and Past Occupational Exposure to Asbestos" ${ }^{17}$ included the following tables showing the "Odds Ratios" ("OR") from various smoking and asbestos-related factors, based on both a univariate and multivariate analysis:

Table 37: Lung Cancer Odds Ratio
TABLE 2
Unt- and multivarlate prediction of histologic type (adenocarcinoma versus squamous-cell carcinoma) with indicators of occupational asbestos exposure and tobacco smoking

|  |  | Univariate |  | Multivariate |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Predictor | NEC | OR | 95\% CI | OR | 95\% CI |
| Asbestos exposure ( $\geqslant 1$ million $\mathrm{f} / \mathrm{g}$ dry wt of lung) | 15 | 2.99 | 1.10-8.09 | 3.03 | 1.09-8.47 |
| Mean lifetime daily smoking ( $>20$ cigarettes/d) | 7 | 0.83 | 0.28-2.45 | 0.61 | 0.18-2.03 |
| Duration of smoking ( $>43 \mathrm{yr}$ ) | 10 | 0.85 | 0.32-2.28 | 0.93 | 0.32-2.69 |
| Time from cessation of smoking to clinical appearance ( $a 5 \mathrm{yr}$ ) | 8 | 1.43 | 0.48-4.42 | 1.27 | 0.40-4.04 |
| Age at onset of smoking ( $<18 \mathrm{yr}$ ) | 14 | 1.29 | 0.50-3.38 | 1.29 | 0.45-3.66 |

Includes ever-smoker men, adenocarcinoma, and squamous-cell carcinoma histologies only. All predictors are included in the multivariate models. Excludes subjects with missing data in any variable in the analysis.
Predictor, exposed category given in parentheses.
NEC , number of exposed cases.

[^11]TABLE 3
Uni- and multivariate prediction of p 53 mutations with histologic type and indicators of occupational asbestos exposure and tobacco smoking

|  |  | Univariate |  | Multivariate |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Predictor | NEC | OR | 95\% CI | OR | $95 \% \mathrm{Cl}$ |
| Histologic type (adenocarcinoma) | 10 | 0.41 | 0.15-1.09 | 0.42 | 0.14-1.28 |
| Asbestos exposure ( $\geqslant 1$ million $\mathrm{f} / \mathrm{g}$ dry wt of lung) | 11 | 0.47 | 0.18-1.23 | 0.69 | 0.23-2.06 |
| Mean lifetime daily smoking ( $>20$ cigarettes/d) | 7 | 0.41 | 0.15-1.10 | 0.58 | 0.17-2.00 |
| Duration of smoking (>43 yr) | 19 | 3.23 | 1.19-8.79 | 2.87 | 0.98-8.40 |
| Time from cessation of smoking to clinical appearance ( $\geqslant 5 \mathrm{yr}$ ) | 7 | 0.53 | 0.18-1.57 | 0.82 | 0.24-2.78 |
| Age at onset of smoking ( $<18 \mathrm{yr}$ ) | 13 | 0.38 | 0.14-0.98 | 0.45 | 0.16-1.31 |

TABLE 6
Uni- and multivariate prediction of $\mathrm{K}-\mathrm{ras}$ mutations with histologic type and indicators of occupational asbestos exposure and tobacco smoking

|  |  | Univariate |  | Multivariate |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Predictor | NEC | OR | 95\% CI | OR | 95\% CI |
| Histologic type (adenocarcinoma) | 15 | 24.4 | 4.87-122 | 36.6 | 5.79-232 |
| Asbestos exposure ( $\geqslant 1$ million $\mathrm{f} / \mathrm{g}$ dry wt of lung) | 9 | 2.25 | 0.74-6.87 | 1.02 | 0.22-4.71 |
| Mean lifetime daily smoking ( $>20$ cigarettes/d) | 7 | 2.05 | 0.65-6.48 | 3.93 | 0.58-26.7 |
| Duration of smoking ( $>43 \mathrm{yr}$ ) | 5 | 0.60 | 0.18-1.94 | 0.53 | 0.11-2.65 |
| Time from cessation of smoking to clinical appearance ( $\approx 5 \mathrm{yr}$ ) | 4 | 0.90 | 0.25-3.25 | 0.49 | 0.09-2.74 |
| Age at onset of smoking ( $<18 \mathrm{yr}$ ) | 10 | 1.74 | 0.57-5.29 | 1.13 | 0.23-5.66 |

See footnotes to Table 2.

In this study, adenocarcinoma (which is the most common type of lung cancer) had a statistically significant impact from asbestos exposure. As shown in table 2 above, the odds ratio is about 3 , with a $95 \%$ confidence interval that is wholly above 1 .

As shown in table 6 above, the K-ras mutation that has a very strong link with adenocarcinoma (about 30 times more likely to produce this type of cancer), however indicated almost unity (i.e. no link) with asbestos exposure on a multivariate basis. This stands in stark contrast to the impact of mean lifetime daily smoking, which was a strong predictor. It should be noted, however, that there was a wide $95 \%$ confidence interval of this odds ratio that encompassed possible figures up to 4.71 , and hence there could be an impact from asbestos exposure.

By contrast, in this study there was no evidence that a p53 mutation (which tends to indicate types of lung cancer other than adenocarcinoma) had any correlation with asbestos exposure, with the $95 \%$ confidence interval of the odds ratio running from 0.23 to 2.06 and centring on 0.69 . For this type of mutation, the duration of smoking appeared to be the key predictor, as shown in table 3 above.

## Age of Diagnosis and Asbestos-Related Latency

A further note of interest from the above study (a point that also appears to be backed up by other studies and the data collated by the Working Party), is related to the age of lung cancer sufferers. The medical study indicated an age of diagnosis in the mid-60s regardless of asbestos exposure as shown in the following table from the study:

Table 38: Lung Cancer Fibre Concentration
TABLE 1
Demographic and exposure data on lung cancer patients by pulmonary asbestos fiber concentration

|  | Pulmonary Concentration of Asbestos Fibers |  |
| :--- | :---: | :---: |
|  | $>1.0 \times 10^{5}$ <br> $(f / g)$ | $<1.0 \times 10^{5}$ |
| $(f / g)$ |  |  |
| Sex (M/F) | $33 / 0$ | $54 / 15^{*}$ |
| Age at diagnosis | $64 \pm 7$ | $63 \pm 9$ |
| Smoking (mean $\pm$ SD) |  |  |
| $\quad$ Cigarettes smoked/d | $25 \pm 12$ | $20 \pm 9$ |
| $\quad$ Pack-years | $44 \pm 24$ | $41 \pm 22$ |
| $\quad$ Yr since quitting | $6.8 \pm 12$ | $2.6 \pm 6.3$ |
| $\quad$ Age at starting | $18 \pm 4.3$ | $18 \pm 6.0$ |
| Pulmonary fiber content | $11 \pm 28$ | $0.3 \pm 0.2^{\dagger}$ |
| $\quad$ Mean $\pm$ SD | $11 \pm$ |  |
| $\quad$ Median | 2.2 | 0.3 |

* For one female patient, no data available for asbestos exposure.
${ }^{\dagger}$ Fiber concentration below detection limit ( $0.3 \times 10^{6} \mathrm{f} / \mathrm{g}$ ) taken into account as $0.5 \times 0.3 \times 10^{5} \mathrm{f} / \mathrm{g}$.

All sources similarly back up a fairly tight range around the mid-60s to early-70s as the age for diagnosis, regardless of the underlying cause. Our data (which is asbestos-related only, since it deals with asbestos-related claims) indicates a typical age of claiming for lung cancer at about 67-68, which is consistent with the study, although the trends for the average and upper ages have been gradually upwards from 1990 to 2008 as shown in the following graph:

Figure 35: Average Age of Lung Cancer Claimants by Year of Notification

Although the claims data indicates a gradual upward trend in the average age of claimants, the minimum age has remained remarkably steady with only one year ever offering a claimant under the age of 55. If a mesothelioma-style "incubation period" applied, we would expect to see those claims at considerably younger ages from those exposed whilst in their teens.

Data from total UK deaths obtained from Cancer Research UK shows a similar stable trend in average age, moving from 61.9 and 71.1 for diagnosis and death respectively in 1990 to 62.1 and 72.8 respectively in 2007 - figures that are all consistent with the claimant ages in our data.

Certainly, the traditional view of lung cancer as having a latency of 20 years (as was suggested in the 2004 Working Party paper) doesn't seem to have supporting evidence in the data. In fact, it is difficult to trace back the original source of the "20 year" statistic, with sources generally quoting it without attribution. If there really were such a latency period, there should be a bulk of claimants diagnosed in their 30s and 40s, whereas actually there are none at these ages at all.

Combined with the ages indicated by the work-related asbestos exposure medical study, there is real evidence that the age at which lung cancer manifests itself is relatively independent of the timing of any asbestos exposure. The upward drift in claimant age seen in our data is more likely due to underlying downward trends in smoking, meaning that the average age of the most at-risk population is gradually drifting upwards.

## Conclusions of Investigations

There is considerable uncertainty about the interaction of smoking and asbestos. This uncertainty is in no small part related to the tendency to treat all lung cancers under the same umbrella when projecting claims.

Two features stand out, however:

1. Smoking remains the key driver of lung cancer deaths, although exposure to asbestos does also seem to generally increase the likelihood of contracting the disease.
2. The age at diagnosis does not seem to be affected by the timing of any asbestos exposure.

In conclusion, projecting lung cancer claims seems to be above all a matter of understanding smoking trends. Layered onto this needs to be an understanding of the factors that affect claim intensity:

- Exposure of the claimant to asbestos. It is important to note that the asbestos may not have actually "caused" the lung cancer - so long as the exposure exists, a claim can be made. As such, we are purely interested in exposure patterns.
- Propensity to claim. If this is a key factor in projecting mesothelioma claims, it can be considered even more so for lung cancer claims since, relatively speaking, considerably fewer cases ultimately manifest as claims. This makes the projection more sensitive to small changes in this assumption.

The importance of these latter factors suggests a possible methodology. It is pragmatic to base the lung cancer projections on the mesothelioma projections. Inbuilt into the mesothelioma projections are a measure of the underlying population's exposure to asbestos and the relative impact thereof, which will define the population that may make a claim. The mesothelioma projections also include a measure of the propensity to claim and the trend of this over time.

As noted, however, it is crucial that we superimpose onto any projection produced in this way an adjustment for changes in smoking exposures. It will also be necessary to adjust for the impact of the difference between mesothelioma and lung cancer trends in claimant age and propensity to claim.

### 8.1.3. Data

## Smoking Data

The key dataset that must be produced is a measure of smoking exposure. To this end, it is vital to have a measure of the level of smoking by calendar year and by age. We obtained the following data relating to smoking rates per 100 population from the $\mathrm{ONS}^{18}$ :

Table 39: Smoking Rates per 100 Population

|  | Men | $\mathbf{1 6 - 1 9}$ | $\mathbf{2 0 - 2 4}$ | $\mathbf{2 5 - 3 4}$ | $\mathbf{3 5 - 4 9}$ | $\mathbf{5 0 - 5 9}$ | $\mathbf{6 0 +}$ |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 1948 | 65 |  |  |  |  |  |  |
| 1980 | 42 | 33 | 44 | 47 | 45 | 45 | 34 |
| 1982 | 37 | 31 | 39 | 40 | 39 | 41 | 32 |
| 1984 | 35 | 28 | 39 | 39 | 38 | 38 | 29 |
| 1986 | 34 | 30 | 41 | 37 | 37 | 34 | 28 |
| 1988 | 32 | 28 | 37 | 37 | 36 | 32 | 25 |
| 1990 | 31 | 28 | 39 | 37 | 34 | 27 | 24 |
| 1992 | 29 | 29 | 39 | 35 | 31 | 27 | 20 |
| 1994 | 28 | 28 | 42 | 34 | 31 | 26 | 17 |
| 1996 | 28 | 25 | 43 | 38 | 30 | 27 | 17 |
| 1998 | 28 | 30 | 42 | 37 | 32 | 26 | 15 |
| 2000 | 29 | 30 | 40 | 38 | 33 | 27 | 16 |
| 2001 | 29 | 30 | 36 | 39 | 31 | 27 | 16 |
| 2002 | 28 | 24 | 39 | 38 | 31 | 25 | 16 |
| 2003 | 27 | 22 | 38 | 36 | 29 | 26 | 16 |
| 2004 | 27 | 26 | 38 | 37 | 31 | 25 | 15 |
| 2005 | 26 | 25 | 37 | 34 | 31 | 25 | 15 |
| 2006 | 25 | 23 | 34 | 33 | 29 | 25 | 14 |

From this data, we interpolated and extrapolated trends to apply by age group from 1948 to 2050. This was applied to the same population projection used in the mesothelioma projections to establish numbers of smokers by age for each calendar year.

The "smoking exposure" applicable to lung cancer projections may be to do with numbers of packets smoked, to do with duration of smoking or some other combination of factors. We have produced a generic exposure by selecting an age of diagnosis ("X") for a given year ("Y") and summing smoker populations across all previous years for those who are age X as at year Y , thus creating a birth cohort effect.

A feature of taking this approach is a "spike" in smoker exposure at about 2015-2019. There was a large, sudden increase in the birth rate in 1947 and these children would be 16 in 1963. Assuming an age of diagnosis of 68 , for example, this means that this "baby boom" hits the lung cancer statistics in 2015. Working against this, however, is the steadily decreasing smoking rates, which act to reduce aggregate smoker exposure at age 68 after that time. The result is a rapid increase in relative smoking exposure in the late 2010s followed by a rapid decline thereafter.

These demographics also predict that we are currently in a temporary lull for smoking exposure, due to it being about 68 years after the period of the Second World War. If the model is right, this would predict that there should currently be a temporary lull in the incidence of lung cancer claims.

The following table shows the relative smoking exposure produced in this way, an average of the exposures calculated using diagnosis ages of 65 to 71 inclusive.

[^12]Table 40: Relative Smoking Exposure

| Year | Smoking Exposure Relative to 2008 |
| :---: | :---: |
| 1997 | $116 \%$ |
| 1998 | $113 \%$ |
| 1999 | $110 \%$ |
| 2000 | $108 \%$ |
| 2001 | $106 \%$ |
| 2002 | $104 \%$ |
| 2003 | $103 \%$ |
| 2004 | $103 \%$ |
| 2005 | $102 \%$ |
| 2006 | $100 \%$ |
| 2007 | $100 \%$ |
| 2008 | $100 \%$ |
| 2009 | $101 \%$ |
| 2010 | $102 \%$ |
| 2011 | $103 \%$ |
| 2012 | $110 \%$ |
| 2013 | $114 \%$ |
| 2014 | $115 \%$ |
| 2015 | $115 \%$ |
| 2016 | $114 \%$ |
| 2017 | $113 \%$ |
| 2018 | $108 \%$ |
| 2019 | $104 \%$ |
| 2020 | $101 \%$ |
|  |  |

In practice, we constructed exposure relativities for a range of ages at diagnosis. These were applied to produce a range of claim number projections. The scenarios quoted in the results section are an amalgamation of these.

## Claim Data

In order to use the mesothelioma model to project lung cancer claims, it is necessary to establish an underlying mesothelioma-to-lung cancer claim ratio. The history of lung cancer claims was taken from the data collection exercise (see Section 3.4.2). This dataset also included details on average claim payments over the same time.

The minimum, maximum and average ages of claimants in the dataset is shown in the graph in Section 8.1.2. These were used to inform the selection of age at diagnosis, which was the driver of the smoking adjustment. Various different ages at diagnosis were tested and the final selected projections are an amalgamation of the results of these.

## Mesothelioma Model

The mesothelioma projections, detailed elsewhere in this paper, were used as a basis for our projections.

### 8.1.4. Supporting Evidence for Methodology

Having derived the smoking exposure shown in the table above, it is possible to examine recent trends in total UK lung cancer deaths to see if the exposures stand up to the real-world experience.

The following graph shows recent UK lung cancer deaths (data from Cancer Research UK) and the same figures adjusted using the smoking exposure quoted above. It indicates that the exposure adjustment's normalisation of the observed trend in total deaths is successful, with the post-adjustment figures occurring at a fairly stable level whilst the original data shows a distinct downward trend.

Figure 36: Lung Cancer Death Rates

The website of Cancer Research UK also contains their projections of total UK Lung Cancers ${ }^{19}$. This backs up the concept that although incidence rates are falling due to smoking trends, population statistics mean that total incidences will rise in the immediate future, with the current time period forming a trough in the figures. Below, we reproduce the relevant males-only table from that report (Table Two on page3; note that this is a table of new diagnoses, rather than deaths and hence is not consistent with the above chart).

Table 41: Cancer Research UK Total UK Projection of Lung Cancers

|  | Year of Diagnosis | Rate per 100,000 males | Average number of cases per year*, GB | Average number of cases per year*, UK - |
| :---: | :---: | :---: | :---: | :---: |
|  | 1975-79 | 113.0 | 30,564 | - |
|  | 1980-84 | 111.0 | 31,140 | - |
|  | 1985-89 | 102.2 | 29,797 | - |
|  | 1990-94 | 90.5 | 27,401 | - |
|  | 1995-99 | 76.6 | 24,337 | 24,883 |
|  | 2000-04 | 66.1 | 22,390 | 22,930 |
|  | 2005-09 | 57.1 | 21,004 | 21,533 |
|  | 2010-14 | 51.5 | 20,743 | 21,279 |
|  | 2015-19 | 48.4 | 21,358 | 21,923 |
|  | 2020-24 | 47.8 | 22,898 | 23,515 |

*The annual case numbers are an average of the number of overall cases in each five-year period (i.e. the overall figure
has been divided by five). has been divided by five).
~ Data for the whole of the UK is only available from 1993 onwards.

[^13]The asbestos-related deaths will not see the same upwards pressure on the long-term population trends that are associated with the UK as a whole, since asbestos exposure reduced rapidly after the 1970s, thus reducing the pool of potential sufferers. Nevertheless, Cancer Research UK's investigation is instructive for the illustration that a reduction in smoking rates (and hence incidence and death rates) does not necessarily correspond with a reduction in the total number of lung cancer cases.

### 8.1.5. Methodology - Claim Numbers

The approach is a pragmatic one, which aims to bring together trends in smoking with trends in asbestos exposure and propensity to claim. Other methods would also be possible and some may even be more appropriate.

For a more complete understanding of the underlying drivers of claims, it would be necessary to construct models similar to those used by the Working Party to project mesothelioma claims. These would need their own parameterisations for each element of the model. We have not done this since lung cancer claims only form a small portion of the total asbestos claims. Nevertheless, we believe that the pragmatic approach taken here provides some insight as to the nature of lung cancer claims and their possible future evolution.

The methodology is:

- Use historic mesothelioma and lung cancer claim data to produce crude "lung cancers per mesothelioma" rates for each calendar year.
- Estimate smoking rates at each age in the UK in each calendar year.
- Apply to population data to obtain smoking population per age per year.
- Select "Diagnosis Age" for lung cancer.
- Sum smoking population across birth cohorts to get total historical smoking exposure as at Diagnosis Age for each calendar year.
- Apply relative exposure to crude "lung cancers per mesothelioma" rates to reverse impact of smoking trends ("smoking-normalised rates")
- Two key trends remain:
i) The movements in the relative likelihoods of death; and
ii) The movements in the relative propensities to claim.
- The former is related to incubation of lung cancer versus mesothelioma and is likely to be a long-term trend, whereas the latter is to do with relative tendencies to claim and is likely to be made up of a series of short-term trends.
- These trends should be applied to the smoking-normalised rates in order to establish the "final adjusted observed rates".
- If all trending has been done properly, the result should be a stable figure over time, with no clear trend. If it is not stable, revisit the assumptions for the underlying trends. The stable figure is the "underlying lung cancer per mesothelioma rate".
- Apply this underlying rate to the projected future mesothelioma deaths to get an adjusted projection of future lung cancer claims.
- Apply the trends into the future to get final projected lung cancer claims.
- This is repeated for several different Diagnosis Ages and a final, smoothed, projection chosen.

The trend in the relative likelihood of death is to do with the relative size of the "at-risk" population that has been exposed to asbestos. This is chiefly related to the nature of the Diagnosis Age:

- Diagnosis Age affects likely historical asbestos exposure. This is particularly important in the tail, since:
i) If mesothelioma has a latency of 40 years after exposure; whereas
ii) Lung cancer Diagnosis Age is either static or increasing only slowly; then
iii) Since asbestos exposure steadily declined from the 1970s, the proportion of lung cancer sufferers exposed to asbestos at the Diagnosis Age will gradually reduce compared with the proportion of at-risk mesothelioma sufferers that were exposed to asbestos.
- Age also directly concerns population size. For example, if:
i) Lung cancer Diagnosis Age is 68; whereas
ii) The average mesothelioma Diagnosis Age for that particular calendar year is 75; then
iii) There will be fewer people available to contract mesothelioma in the general population than are available to contract lung cancer.

This trend is long term. We can experiment with different types of trend to obtain the best fit.
Having eliminated the long term trend of relative likelihood of death, the remaining trend is reporting tendency. Lung cancer has a lot more potential for future increases than mesothelioma has in its propensity to claim, so there is a distinct potential for the "lung cancer per mesothelioma" rate to increase in the future.

Several factors combine to justify the idea that large potential future increases in the reporting trend are possible:

- The number of lung cancer deaths being claimed for as asbestos-related is a tiny fraction of the total pool of all lung cancer deaths - about 1\% in total.
- The vast majority of these deaths will be smoking-related. This smoking link means that we can expect to continue to see the total lung cancer deaths across the UK to remain high for quite some time. Regardless of whether the underlying cause was wholly or partially smoking, however, any exposure to asbestos will allow for an asbestos-related claim to be made.

Despite the potentially large pool of claimants, however, it is largely trends in public awareness and attitude that will dictate how the propensity to claim changes and this is particularly difficult to predict.

The manner in which the trend in the propensity to claim is related to the focus of media reporting means that the reporting trend is actually likely to be made up of a composite of shortterm trends. Again, we can experiment with different types of trend to obtain the best fit.

### 8.1.6. Methodology - Claim Amounts

The claim number approach projects all lung cancer claims, including nil claims (since it is based on notifications). As such, we need to use an average claim amount including nil claims. We used the summary data to establish the average claim amount applicable to the last five years. We then applied several alternative claim inflation assumptions to this average claim amount in order to establish average claim amounts for each future calendar year.

The current average cost per claim is running at just over $£ 40,000$.

We have illustrated results using claims inflation of 1\%, 3\% and 5\% per annum, as we believe these are reasonable alternative future inflation estimates based on the mesothelioma analysis. Although all the comments about inflation made in the mesothelioma section of this paper also apply here, it is worth noting in addition that if there is a trend towards a greater proportion of claims being more smoking- than asbestos-related then this will result in a greater proportion of awards being reduced for contributory negligence and this will, in turn, act as a negative inflationary pressure on the average claim amount. As such, it may be more appropriate to consider a lower future inflation assumption for lung cancer claims than for mesothelioma claims.

### 8.1.7. Range of Results

The methodology contains considerable sources of uncertainty. These include, but are not limited to the following:

- The smoking exposure we have used is an approximation only for the true underlying risk measure for smoking.
- Smoking trends have been extrapolated from incomplete data.
- The population used does not have direct correspondence to the at-risk population, who may have different smoking rates to the general population.
- The nature of the asbestos exposure for lung cancer sufferers may be different to that of mesothelioma sufferers, meaning that the mesothelioma model is an inappropriate basis.
- The trends used to adjust movements in relative mesothelioma and lung cancer incidence rates over time may be incorrectly parameterised or simply wrong in nature.
- The trends used to adjust movements in relative mesothelioma and lung cancer propensity to claim rates over time may be incorrectly parameterised or simply wrong in nature.
- Reductions for contributory negligence make predicting trends in average claim amounts particularly difficult here - a fact that is exacerbated by the dominance of the effect of smoking on the projected results.

We have allowed for some element of parameter uncertainty (although not process error or model error) by running our model with different assumption sets, to provide a range of estimates. This range represents various reasonable outcomes; it is not intended to suggest "optimistic" or "pessimistic" scenarios or an upper or lower bound.

The following table demonstrates a cross-section of such outcomes:
Table 42: Lung Cancer Projection Results

| Projection Summary (£m) |  | Inflation Assumption |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Scenario | Total <br> Projected <br> Claims | $\mathbf{1 \%}$ | $\mathbf{3 \%}$ | $5 \%$ |
| Scenario 1 | 3,799 | 171 | 201 | 238 |
| Scenario 2 | 8,378 | 395 | 512 | 679 |
| Scenario 3 | 19,504 | 952 | 1,332 | 1,913 |

The reader may note that the range is much wider in relative terms than the mesothelioma range of results. This is because many of the parameters associated with the prediction of lung cancer have such great scope for adjustment within reasonable bounds.

This makes sense from a wider perspective too -- only about $1 \%$ of all lung cancers result in an asbestos-related claim. Clearly there is plenty of scope for change above a figure of $1 \%$, and yet if this were to change from $1 \%$ to $2 \%$ then the predicted cost would double.

Scenario 1 contains a heavy age-related component, i.e. it assumes that the pool of potential lung cancer claimants reduces $7 \%$ faster than the pool of potential mesothelioma claimants. It also assumes no change in the propensity to claim.

Scenario 2 contains a small age-related component, i.e. it assumes that the pool of potential lung cancer claimants reduces $2 \%$ faster than the pool of potential mesothelioma claimants. It allows for the trend in propensity to claim seen in the last five to seven years to continue for another few years.

Scenario 3 contains a smaller still age-related component, i.e. it assumes that the pool of potential lung cancer claimants reduces just $1 \%$ faster than the pool of potential mesothelioma claimants. In addition, it also allows for a heavy increasing trend in the propensity to claim $10 \%$ per year for the next ten years.
Below we show the claim number graphs that relate to Scenarios 1, 2 and 3:
Figure 37: 2009 Working Party Asbestos-Related Lung Cancer Claim Number Projections

The wide dispersal of these graphs demonstrates that there is considerable uncertainty in relation to the future Insurance Market cost of asbestos-related lung cancer claims.

The above may appear to be the output of a complicated analysis, but the complexity should not be seen as giving additional credibility to the projections. It is not possible to forecast accurately how claim notifications may trend in the future; all the scenarios shown above are plausible. Indeed higher or lower projections can also be derived. It has been often quoted that there could be one asbestos-related lung cancer case for every mesothelioma case. If this is true and the propensity / ability to claim against former employers or their insurers equals that seen for mesothelioma claims then future claim numbers could exceed those projected in Scenario 3.

### 8.1.8. Comparison to 2004 Working Party Results

The data available for the 2004 Working Party study was less refined than that available for the 2009 study. There were only a few years of reliable lung cancer data available; prior to that an estimate had to be taken from a general "non-mesothelioma" data set.

In addition, the 2004 Working Party study did not consider the combined effects of smoking trends and population changes, particularly the baby boom that occurred just after the Second World War. Instead, it concentrated on broad observed trends in lung cancer claims. Using this approach, the mid-estimate was for claim levels to be flat until 2016 and decrease thereafter. This position was not unreasonable (aforementioned issues with data aside) and is similar in concept to Scenario 1 in our revised estimates.

The 2004 Working Party study projected claim numbers that materially undershot the true picture from 2004 to 2008, as the following graph demonstrates. This graph shows the original "actual" lung cancer claim numbers and the true actual lung claim numbers, as well as the projections made in the 2004 Working Party study.

The chief reason for this under-projection for the period from 2004 to 2008 seems to be the quality of the data - had the true 2003 picture been known, it is very unlikely that the selected projections would have been chosen.

Figure 38: 2004 Working Party Asbestos-Related Lung Cancer Claim Number Projections

Unsurprisingly, this undershooting of the true position was also reflected in materially lower estimates for the future claims than under our revised scenarios. Below, we show the 2004 estimates (as they relate to post-2008 claims only):

Table 43: Lung Cancer Projection Estimates made in 2004

| Original 2004 Projection <br> Summary (£m) |  | Inflation Assumption |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Scenario | Total <br> Projected <br> Claims | $\mathbf{0 \%}$ | $\mathbf{4 \%}$ | $\mathbf{8 \%}$ |
| Scenario 1 | 455 | 17 | 26 | 38 |
| Scenario 2 | 1,650 | 63 | 115 | 220 |
| Scenario 3 | 2,959 | 112 | 264 | 706 |

The change in the selected projected cost for asbestos-related lung cancer claims is around $£ 400 \mathrm{~m}$. This is due both to the deterioration in claims experience since 2004 as well as a different view in respect to the future projection of asbestos-related lung cancer claims.

As mentioned above, the curve used for the 2004 Working Party study was similar in concept to our revised Scenario 1, which had an estimate of about $£ 220 \mathrm{~m}$ at an inflation rate of $4 \%$ per annum. We may therefore break down the $\times 4$ change in estimate into factors of $\times 2$ due to changes in data and a further $\times 2$ due to a change in methodology.

It is re-iterated that all 2009 scenarios presented are plausible and should not be considered as either optimistic or pessimistic, or an upper or lower bound.

### 8.2. Asbestosis

### 8.2.1. Summary

Compared to other asbestos-related diseases, projections of the number and cost of asbestosis Insurance Market claims have proved somewhat more reliable. Asbestosis Insurance Market claims do not appear to have been affected by the changes in the propensity to claim that have characterised mesothelioma and lung cancer claims, and, as discussed in Section 3.4.3, the actual number of claims presented in the 2004-2008 period and the corresponding incurred amounts are broadly comparable with the projections of the 2004 Working Party.

However, there remains significant uncertainty in respect of future projections, both affecting potential claim numbers and their average cost. Hence, we selected a combination of potential scenarios that represent reasonable forecasts of the development of asbestosis claims. These are discussed in more detail in the following sections.

Table 44: Asbestosis Projection Results

| Projection Summary (£m) |  | Average Cost Per Claim |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | 16,000 | 18,750 | 22,000 |
| Scenario | Total <br> Projected <br> Claims | $1 \%$ | $3 \%$ | $5 \%$ |
| Scenario 1 | 13,227 | 227 | 309 | 425 |
| Scenario 2 | 20,224 | 354 | 503 | 726 |
| Scenario 3 | 34,867 | 627 | 940 | 1,437 |

The new projections are comparable to the forecasts by the 2004 Working Party, which ranged between $£ 291$ and $£ 1,274$ million over the period from 2009 to 2040 period, with a central projection of $£ 512$ m.

### 8.2.2. Background Issues and Data Sources

Asbestosis is defined as a bilateral diffuse pulmonary fibrosis caused by a sufficiently high cumulative exposure to air-borne asbestos fibres. Contrary to diseases such as mesothelioma, the likelihood of developing asbestosis is not generally thought to be significantly affected by the length of the exposure period and the time elapsed since first exposure. Instead, the latency period tends to be inversely proportional to the exposure level. Asbestosis is also known to be negatively affected by smoking ${ }^{20}$, both in terms of likelihood of contracting the disease and of its progression rate - although not necessarily its mortality rate ${ }^{21}$.

Finally, since asbestosis is a degenerative progressive disease that only in the most severe cases can lead to death, it is important to distinguish between the onset of the disease and death, often with considerable time passing between the two. In terms of insurance claims, manifestation is most relevant, since a claim can be presented after proper diagnosis, while the severity of the disease will affect compensation levels.

[^14]Early asbestosis cases tended to be associated with occupational exposure to extremely high concentrations of asbestos fibres (e.g. aboard ships during or after the Second World War), with the disease manifesting itself after relatively short latency periods of between five and twenty years ${ }^{22}$. It is very unlikely that many such cases are still occurring; current asbestosis cases are more likely to be caused by exposures to lower levels of asbestos fibres for long periods of time. This type of occupational exposure is known to be associated with much longer latency periods, e.g. Selikoff and collaborators found in their classic 1980 study on insulation workers ${ }^{23}$ that asbestosis deaths in the cohort they observed peaked 40 to 45 years after first exposure. Current asbestosis sufferers were likely to be exposed to even lower annual fibre concentrations, hence the significant latencies implied in the still high number of new cases. However, it is expected that the number of asbestosis cases should start declining earlier, and faster, than the number of mesothelioma cases.

These and other considerations led the 2004 Working Party to hypothesise that the peak of asbestosis claims had already been reached in the UK, well in advance of the peak of mesothelioma deaths which is expected to occur in the second decade of this century.

In order to validate this hypothesis we looked at a number of data sources. The main data source was the survey data collected by the Working Party as set out in Section 3.

The data confirms that claims have started to decrease in recent years, having reached a peak in 2003. Some issues remain with the reliability of the survey data; while data quality in recent years (2004 and post) is thought to be high, data in earlier years is not as reliable, especially as far as the exact identification of the claim type is concerned. The conclusion that asbestosis claims seem to be past their peak appears strengthened by its independence from the actual data adjustments performed.

We also looked at the number of asbestos-related pneumoconiosis claims assessed by the Department for Work and Pensions under the Industrial Injuries Scheme (IIDB) ${ }^{24}$. These claims have been decreasing in the last two years in the dataset, having possibly peaked in 2004.

Finally, we looked at counts of death certificates mentioning asbestosis, as provided by the $\mathrm{HSE}^{25}$. Here, the evidence is less clear, since death counts seem to have been slowly increasing in the last 30 years, with a noticeable increase since 2005, although the 2007 figure is lower than the figure in 2006. Since the increase in death counts is perhaps more evident in the number of certificates mentioning asbestosis as a non-underlying cause of death, it is possible that some diagnostic effect is reflected in the data.

The data discussed above is presented in the following graph. We included the number of mesothelioma insurance claims for comparison purposes, since the latter display a protracted steep rise, which we believe has been magnified by increases in the propensity to claim which do not seem to have had such a role in the asbestosis claims dynamics.

[^15]Figure 39: Asbestosis Insurance Claims, Population Deaths, IIDB Awards

### 8.2.3. Methodology - Claim Numbers

Asbestosis claims have been decreasing since their 2003 peak, although the exact extent of the reduction in the number of asbestosis claims in the last ten years is affected by the selected adjustment to our past survey data. As discussed in Section 3.4.3, the cumulative number of claims filed in 2004-2008 is quite close to the number of claims in the 2004 Working Party medium projection (adjusted to reflect the most recent data). This projection had been derived from a parameterisation of the 2004 Working Party simplified epidemiological (HLM) model which still appears reasonable, hence we included it as our projection Scenario 2.

Significant uncertainty remains about future developments, relating both to the uncertainty in epidemiological estimates (e.g. the long term trends might be better represented by death numbers, which do not appear to be reducing much at all, or alternatively they could decrease more rapidly than expected) and to potential changes in the propensity to claim. We endeavoured to capture this by including plausible best estimate Scenarios 1 and 3. The former, similarly to the pleural thickening case 1, assumes that claims are past their peak and will decrease until 2020 at a rate derived from the original HSE 2009 asbestos exposure curve with a 42 year lag; after 2020, we assumed the 2004 Working Party low pattern would apply.

Our Scenario 3 assumes that claims have still to reach their peak and will increase until 2012 at a similar rate to mesothelioma deaths, followed by a decreasing pattern modelled based on the 2004 Working Party high scenario (with a somewhat steeper gradient after 2025). Scenarios 2 and 3 allow for a limited number of claims to be filed between 2040 and 2050.

The following graph summarises past claims experience and our range of projections.
Figure 40: 2009 Working Party Asbestosis Claim Number Projections

### 8.2.4. Methodology - Claim Amounts

The average incurred (on a notification year basis) and paid (excluding nil claims, on a settlement year basis) costs of asbestosis claims in our survey data are reasonably consistent and are currently around $£ 22,000$ and $£ 21,000$ respectively. However, since our claim projection methodology produces forecasts including rejected/dismissed (nil) claims, some adjustments in our average severity assumption appear warranted.

The survey data suggests that as many as $30 \%-40 \%$ of filed asbestosis claims are eventually dismissed. However, it is unclear that such a reduction should be applied in full to average severities. For example, it is arguable that incurred but unpaid amounts should already include some allowance for future dismissals, although this will depend on actual company practices, and the cost of actual resolved claims should be automatically reflected in the observed averages.

In order to better account for the uncertainty in future average asbestosis claim costs, we selected three different starting average values. In case A, we chose an initial value of $£ 16,000$, corresponding to a current average incurred cost of asbestosis claims, net of the full survey data dismissal rate applied to still unresolved claims. Case $B$ has a starting value of $£ 18,750$, derived by applying approximately half the survey data dismissal rate to the average cost of incurred but unresolved claims. In case C, we selected the full $£ 22,000$ current incurred average cost as our starting point.

Three different sets of inflation rates ( $1 \%, 3 \%$ and $5 \%$ ), which we believe are reasonable alternative future inflation estimates based on the mesothelioma analysis, were then applied to our selected averages, to obtain three different projections of average claims costs.

### 8.2.5. Range of Projections

The results of our projection exercise are reproduced below. The scenarios represent various reasonable outcomes; they are not intended to suggest "optimistic" or "pessimistic" scenarios, or an upper or lower bound.

Table 45: Asbestosis Projection Results

| Projection Summary (£m) |  | Average Cost Per Claim |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 16,000 | 18,750 | 22,000 |
| Scenario | Total <br> Projected <br> Claims | $\mathbf{1 \%}$ | $3 \%$ | $5 \%$ |
| Scenario 1 | 13,227 | 227 | 309 | 425 |
| Scenario 2 | 20,224 | 354 | 503 | 726 |
| Scenario 3 | 34,867 | 627 | 940 | 1,437 |

These projections are similar overall to the ranges produced by the 2004 Working Party. These are summarised in the following table, which only includes projections for the period from 2009 to 2040 for comparison purposes.

Table 46: Asbestosis Projection Results made by 2004 Working Party

| Projection Summary (£m) |  | Average Cost Per Claim |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | Low <br> $\mathbf{1 8 , 0 4 6}$ | Medium <br> $\mathbf{2 0 , 2 9 9}$ | High <br> $\mathbf{2 2 , 7 8 2}$ |
|  |  | Inflation Assumption |  |  |
| Scenario | Total <br> Projected <br> Claims | $\mathbf{1 \%}$ | $\mathbf{3 \%}$ | $\mathbf{5 \%}$ |
| Scenario 1 | 15,087 | 291 | 378 | 496 |
| Scenario 2 | 20,671 | 404 | 539 | 728 |
| Scenario 3 | 32,570 | 649 | 902 | 1,274 |

### 8.3. Pleural Thickening

### 8.3.1. Summary

For completeness we have also estimated the future Insurance Market cost for pleural thickening claims as at 1 January 2009.

The following table sets out our estimate of the potential future Insurance Market cost for pleural thickening claims, in a consistent format as the lung cancer and asbestosis projections:

Table 47: Pleural Thickening Projection Results

| Projection Summary (£m) |  | Inflation Assumption |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Scenario | Total <br> Projected <br> Claims | $\mathbf{1 \%}$ | $\mathbf{3 \%}$ | $\mathbf{5 \%}$ |
| Scenario 1 | 3,475 | 74 | 85 | 98 |
| Scenario 2 | 7,024 | 157 | 197 | 253 |
| Scenario 3 | 11,986 | 276 | 375 | 522 |

### 8.3.2. Methodology - Claim Numbers

The approach used is a judgemental one based on projecting future pleural thickening claim numbers and average claim costs.

Figure 41: 2009 Working Party Pleural Thickening Claim Number Projections

The Working Party summary data survey provided the number of reported pleural thickening claims from 1996 to 2008, for the companies able to provide this data. It was estimated that this survey covered $80 \%$ of the UK Insurance Market. The total number of reported UK pleural thickening claim numbers was estimated by grossing up the survey data.

This indicated that the number of reported pleural thickening insurance claims in the UK may have peaked at around 600 in 2005. Future pleural thickening claim numbers were judgementally selected from 2009 onwards on three scenarios as follows:

Scenario 1: This scenario assumes that future pleural thickening claim numbers continue to decrease at a similar rate to that experienced from 2005 to 2008 and eventually tail off by 2030.

Scenario 2: This assumes a straight line reduction in claim numbers from 2009 to 2040.
Scenario 3: This scenario assumes that future pleural thickening claim numbers increase from the 2008 level until a peak in around 2015 and then tail off by 2050.

### 8.3.3. Methodology - Claim Amounts

The claim number approach projects all pleural thickening claims, including nil claims. As such, we need to use an average claim amount including nil claims. We used the summary data to establish the average pleural thickening claim amount of around $£ 20,000$ in 2008. Three different sets of inflation rates (1\%, 3\% and 5\%), which we believe are reasonable alternative future inflation estimates based on the mesothelioma analysis, were then applied to this average claim amount in order to estimate average claim amounts for each future year.

### 8.3.4. Range of Results

Projecting pleural thickening claims is uncertain. The scenarios represent various reasonable outcomes; they are not intended to suggest "optimistic" or "pessimistic" scenarios, or an upper or lower bound.

### 8.3.5. Comparison to 2004 Working Party Results

The 2004 Working Party study estimated the future insurance cost for pleural plaques and pleural thickening claims combined. See Section 8.4 for comments relating to pleural plaques.

Below, we show the 2004 Working Party estimates for pleural plaques and pleural thickening (as they relate to post-2008 claims only):

Table 48: Pleural Plaques and Thickening Projection Results made in 2004

| Original 2004 Projection <br> Summary (£m) |  | Inflation Assumption |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Scenario | Total <br> Projected <br> Claims | $\mathbf{0 \%}$ | $\mathbf{4 \%}$ | $\mathbf{8 \%}$ |
| Scenario 1 | 900 | 11 | 12 | 14 |
| Scenario 2 | 7,900 | 93 | 107 | 122 |
| Scenario 3 | 30,900 | 366 | 425 | 491 |

### 8.4. Pleural Plaques

On 17 October 2007 the House of Lords decided in Rothwell v Chemical and Insulating Company Limited and Others that asymptomatic pleural plaques could not constitute actionable damage. This decision by the highest UK court meant that employers and, therefore, their insurers were not required to pay compensation for asymptomatic pleural plaque claims.

The consequence of this decision remains uncertain. In England and Wales the Ministry of Justice (MOJ) is consulting on the most appropriate way of supporting people diagnosed with pleural plaques. The initial consultation closed on 1 October 2008 and the MOJ indicated that it would announce a decision once all responses had been fully considered. As at early January 2010, an announcement is still awaited.

Rothwell was an English case and therefore not binding in Scotland. English law is of persuasive authority only in Scotland. In order to prevent the Rothwell judgement applying in Scotland the Scottish Parliament introduced the Damages (Asbestos-related Conditions) (Scotland) Bill on 23 June 2008.

Scottish Parliament passed the Bill on 11 March 2009. The Bill provided that the asymptomatic conditions of asbestos-related pleural plaques, asbestos-related pleural thickening and asbestosis were actionable personal injuries for which damages could be claimed. The Bill received Royal Assent on 17 April 2009.

On 21 April 2009 a number of insurers (AXA, Norwich Union, RSA and Zurich) raised a Petition for Judicial Review in the Outer Court of Session in an attempt to strike down the Damages (Asbestos-related Conditions) (Scotland) Act 2009. Insurers argue that they are directly affected by the 2009 Act; that the Scottish Parliament acted irrationally in bringing in the legislation (contrary to the House of Lords ruling in Rothwell); and further that the Act contravenes their rights to a fair trial and safe possession of property under the European Convention on Human Rights.

The Act came into force on 17 June 2009 but the Judicial Review resulted in existing claims being sisted (stayed). On 8 January 2010, Lord Emslie handed down his Judgment. He ruled that while insurers do have a standing to challenge Acts of the Scottish Parliament, they had otherwise failed to persuade the Court that the 2009 Act should be struck down. The insurers' Petition was therefore dismissed. Insurers have lodged an appeal which will be heard in the Inner House of the Court of Session in Edinburgh probably some time during 2010.

Consultation in respect of pleural plaques has also been made in Northern Ireland, and consideration is currently being made as to whether to adopt similar legislation to that adopted by Scotland.

Due to the recent legal developments for pleural plaque claims there have been limited claim notifications to insurers. This means that it is difficult to make future projections based on actual data. Given this uncertainty, and the fact that asymptomatic pleural plaques are currently not compensable in England, Wales and Northern Ireland, and under a judicial review process in Scotland, the Working Party has not included such claims in its estimates of the Insurance Market cost.

Estimates of the potential cost were included as part of the Government's Consultation on Pleural Plaques. For completeness, the main aspects of these estimates are repeated here:

The MOJ estimate the present value of the cost of compensation and legal costs for both stayed and future pleural plaques ranges between $£ 3,670$ million and $£ 28,640$ million.

## Table 49: Pleural Plaques Projections in MOJ Consultation Paper

This estimate is based on the following assumptions:
Average compensation: $£ 11,500$ to $£ 13,400$ (2008 values)
Average legal costs:
Government stayed cases:
Insurers' stayed cases:
$£ 14,000$ ( $£ 8,000$ for claimants and $£ 6,000$ for defendants)
1,500

Government future cases:
Insurers' future cases (1):
Future cases occur:
Average annual cost:

5,000
10,500
200,000 to 1,250,000
Peak around 2015, 60\% by 2019, 90\% by 2024, 100\% by 2029 $£ 252$ million to $£ 2,022$ million.
(1) The number of future cases is based on the following assumptions:

| Assumption | Low | High |
| :--- | ---: | ---: |
| Exposed to asbestos (2) | $4,000,000$ | $5,000,000$ |
| Develop Pleural Plaques | $25 \%$ | $50 \%$ |
| Number with Pleural Plaques | $1,000,000$ | $2,500,000$ |
| Diagnosed with Pleural Plaques | $20 \%$ | $50 \%$ |
| Number diagnosed with Pleural Plaques | 200,000 | $1,250,000$ |

(2) Note: The population exposed has been estimated by applying a benchmark of $14.6 \%$ based on the US experience (Nicholson WJ, G Perkel and IJ Selikoff (1982), "Occupational Exposure to Asbestos: Population at Risk and Projected Mortality - 1982-2030", Am J Ind Med, 3:259311). Applying the proportion exposed to the UK yields an occupational exposure of around 7.7 million, which has been reduced to 4 million to 5 million taking account of the number who have already died.

The Working Party, on behalf of the Actuarial Profession, produced a formal response to the Consultation Paper. This response can be found on the Actuarial Profession's website at:
http://www.actuaries.org.uk/ data/assets/pdf file/0008/139157/AP MJ PleuralPlaques 20080 930 resp.pdf

## 9. Total Insurance Market Estimates

### 9.1. Summary of results

This section brings together the selected results for the individual disease types described in Section 7 (mesothelioma) and Section 8 (non-mesothelioma) above.

The table below shows the results for all the claim types considered. The inflation 1, 2 and 3 options vary by claim type and are in line with those used in each claim-type specific section. The claim / claimant number scenarios are also set out in each claim-type specific section. It should be noted that the numbers are intended to represent a range of potential central estimates and not a range from low to high. These projections are highly uncertain and it is possible that the ultimate cost could be outside of this range. Further, note that the results illustrated in the table do not include variation due to alternative population deaths projections for mesothelioma claims.

Table 50: Total Insurance Market Projections

| Projection Summary (£m) |  | Inflation Assumption |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Scenario |  | Inflation 1 | Inflation 2 | Inflation 3 |
| Scenario 1 |  | 8,334 | 10,294 | 12,842 |
| Scenario 2 |  | 9,071 | 11,316 | 14,281 |
| Scenario 3 |  | 10,332 | 13,115 | 16,921 |

As described in Section 7, the outcomes encompassed by the 75 mesothelioma scenarios run ranged from a lowest future Insurance Market cost estimate of $£ 4.8$ bn and a highest of $£ 30.0$ bn. Combining these with the lowest and highest non-mesothelioma projections gives an overall lowest Insurance Market cost estimate of $£ 5.3$ bn and a highest of $£ 33.9$ bn.

As noted within the mesothelioma results section the results of these 75 scenarios are for illustrative purposes only. Care should be taken when interpreting the scenario results. They include model selections and assumptions sets which, whilst possible, would not be considered appropriate as a best estimate. The scenario results are not intended to define a set of possible outcomes or to indicate any percentiles that may be used in a stochastic range of results. Possible outcomes may fall outside of the range of results displayed. The quantification of the distribution of possible results has not been considered within this paper.

## 10. Suggestions for future monitoring

In this paper we have outlined the work undertaken to estimate the potential UK Insurance Market cost of asbestos-related claims. The key message emerging from this work is that a large amount of uncertainty surrounds this cost. Although a reasonable estimate of the cost of asbestos-related claims might be of the order of $£ 11 \mathrm{bn}$, there is a large range of uncertainty surrounding this figure as discussed in Section 9. Indeed the uncertainty has not reduced since 2004. A more detailed analysis has only served to highlight but not resolve the areas of uncertainty. Therefore it will be important to monitor the claims experience as it emerges over the next few years.

This section sets out what the Working Party considers to be the most important areas to monitor. It is the Working Party's intention to monitor these areas in the future and to report on any material deviances compared to expectations.

### 10.1. Actual Population Deaths

The actual number of mesothelioma deaths in the British population is published by the HSE each year. The figure is usually published with a lag of about 18 months to two years, for example the 2006 number of deaths was published in late 2008, along with some revisions made to the 2004 and 2005 recorded number of deaths. It was this data that the HSL used to fit their model and produce their projections as discussed in Section 4.4.

Monitoring the total number of deaths will give an early indication as to whether the projections made are reasonable. The HSE published the 2007 number of deaths in October 2009 and this showed that the total number of male deaths was in line with the projections made.

However, it will probably be more revealing to break down the total number of deaths by year of birth / age at death so that the development by year of birth cohort can be compared to that expected. This is important for two reasons. Firstly, it was highlighted in Section 5 that a key assumption was that each year of birth cohort will develop differently in the future and hence the HSL model structure was preferred. If all the year of birth cohorts develop in line with each other in the future, then this would indicate that a simple birth cohort model structure may be a better model. A projection with a different model structure could give rise to significantly different results. Secondly, there is an assumption that the mesothelioma incidence rate (deaths per unit population alive) increases through time. As discussed in Section 4.4, there is a large amount of uncertainty as to what the future incidence rate by year of birth cohort will be, and this is a main driver of the uncertainty within the population death projections due to mesothelioma. Monitoring the actual year of birth incidence rates will help amend the selection of the way the year of birth cohorts develop and hence point to whether the selected future projections require amendment.

We intend to review the developing incidence rates each year as and when the relevant data is available, although it is noted that a yearly analysis will not be as revealing as looking at the development by three year bands due to the high level of random variation that will exist in a single year figure. However, annual developments will give an early indication of the emerging experience ahead of a more robust analysis of the trends.

### 10.2. Population Projections

It was highlighted in Section 4.4 that a large proportion of the increase in the HSL population projections between 2003/5 and 2009 was due to a revision in the overall population projections for Great Britain made by the ONS in 2006. If these projections change in the future, then this will have an impact on the projected level of population mesothelioma deaths - e.g. if it is assumed that a greater number of people are alive at a certain age in the future, then for a fixed mesothelioma incidence rate, it follows that there will be a higher level of mesothelioma deaths.

There are two key aspects to consider here. Firstly, the overall level of longevity assumed in the population projections may not turn out to be as expected. Secondly the overall level might be as expected, but this could vary by year of birth cohort. There has recently been a substantial improvement in the mortality of the year of birth cohort 1930 to 1939. This is also a key cohort within the mesothelioma projections. A continued increase in improvement beyond that expected for this cohort will have an impact on the total population mesothelioma deaths projections. Mortality improvements by year of birth cohort are considered in more detail in the Continuous Mortality Investigation Working Party (Papers 38 and 39). This is an area that is worthy of further investigation and scenario testing.

The Working Party will monitor the updated population projections and other related work and communicate any emerging impacts. For example, an update to the ONS population projections has recently been published, our initial comments on these projections are included as Appendix $G$ to this paper.

### 10.3. Claims to Deaths Ratio

The increase in the proportion of mesothelioma sufferers that claim against employers / insurers that has occurred over the last five years is the main reason for the rise in the estimates of the cost of asbestos-related claims to the Insurance Market. The 2004 Working Party estimates made the assumption that the proportion would remain constant based on past experience, but it has subsequently doubled since 2004. Section 5 discusses the difficulty in estimating how this ratio will develop.

The actual ratio can, however, be easily monitored using the data that is available from the CRU. It is therefore proposed that the Working Party obtains the data from the CRU each year and, linking in with the actual deaths data, sets out how the level of the ratio is trending over time, split by age band. The Working Party will also try and get beneath these trends more by further engaging the relevant parties.

Also, it has been highlighted that there has been a rise in the proportion of female mesothelioma sufferers that are making claims against former employers and their insurers. It has been assumed in the projections made by the Working Party that this proportion remains constant at around $5 \%$ in the future. It will therefore be important to monitor this proportion in the future.

Similarly, the Government has historically received around $20 \%$ of the total number of claimants. The estimate in 2008 for the Government proportion though dropped dramatically to around $16 \%$. We have assumed that this is just a one-off change, and that the future proportion for the Government will remain at the $20 \%$ level. If this proves not to be the case, and the Government has a lower share in the future, then the Insurance Market projections outlined in this paper will prove to be too low. On the other hand, should the Government proportion increase, then the projections will prove to be too high. It is therefore worth monitoring the Government proportion in the future. This can be performed using the CRU data.

### 10.4. Insurance Claim Notifications

The Insurance Market data collection surveys that have been performed by the Working Party have served as a useful check against the expected experience. It has been possible to crossreference the Insurance Market experience with the data obtained from the CRU. Therefore, whilst these market surveys have proved useful, it is believed that the claimant data obtained from the CRU is the most useful way to monitor emerging experience. However, the market surveys conducted are an excellent way to drill down into a level of detail that is not possible by simply using the data obtained from the CRU. Therefore it will be useful to revisit the market surveys in the future, but this does not necessarily need to be done annually. Further requests have been made to the CRU to obtain data in relation to non-mesothelioma claims, and hence the emerging experience for these claims can also be monitored more easily in the future.

### 10.5. Average Claimant Costs

It is recommended that insurance companies start to collect mesothelioma claimant data split by the different heads of claim as set out in Section 6. This will assist with the monitoring of the assumptions underlying the average cost per claim model. This will also enable a much larger sample of claims to be collected in the future which will facilitate a much richer analysis.

## 11. Thanks

A number of people have helped the Working Party members produce this paper. These include Professor Julian Peto of the London School of Hygiene and Tropical Medicine, and John Hodgson, and Andrew Darnton of the HSE. The Working Party would like to thank all of these people for the help and support that they gave to the Working Party.

A special thank you goes to all the companies, and all the people therefore involved, that provided data to the Working Party, and also to Peter Stirling for his help and patience in coordinating the data collection. Similarly, a special thank you also goes to the Association of British Insurers for facilitating the sample of mesothelioma claims data collection.

We would also like to thank the many solicitors, claims handlers, and others within the insurance industry; the Health and Safety Executive; the Compensation Recovery Unit; the Department of Work and Pensions, the professors, clinicians, radiologists and nurses within the NHS and the representatives of voluntary bodies that have helped answer our questions.

## Summary of the 2004 UK Asbestos Working Party Estimates

Our projections of asbestos claim cost build on the quantitative work performed in the original UK asbestos working party paper: "UK Asbestos - The Definitive Guide" which was published at GIRO in 2004.

The 2004 working party estimated that the future cost to the UK insurance industry of UK sourced asbestos-related claims, at that time, was $£ 4 \mathrm{bn}-£ 10 \mathrm{bn}$. Approximately, $70 \%$ of that estimate was in respect of mesothelioma claims. The mesothelioma estimates were based on the HSE's 2003 projection of the future number of mesothelioma deaths. These projections are highly sensitive to a number of key parameters, as is suggested by the wide range of estimates. The projection of population deaths relied on the HSE projection of deaths from mesothelioma, and it was also assumed that the number of mesothelioma deaths that ultimately resulted in an insurance claim remained constant at the past observed average of around one third.

The population projections are also highly sensitive to a number of key parameters. In particular, how the disease continues to develop at older ages, with over half of all projected claims being in respect of those aged over 80 by the year 2020. The working party noted that given the lack of actual experience from that age group, the future number of mesothelioma deaths could easily be considerably higher or lower than the HSE's projections. In addition to using the HSE projections, the working party collected data through an anonymous survey of all major insurers, representing the majority of the UK Employer's Liability market during the main period of asbestos exposure. They derived assumptions for the number of future claims for asbestos-related diseases other than mesothelioma and for the average claim sizes for all asbestos-related disease types. Based on these assumptions the working party derived their estimates for the future cost of asbestos claims to the UK insurance industry.

The 2004 working party did more than just estimate the future cost of asbestos-related claims to the UK insurance industry, and the full paper is available at http://www.actuaries.org.uk/ data/assets/pdf file/0004/34969/Lowe.pdf.

## 2004 mesothelioma estimates

The previous working party's low, medium and high estimates, for the cost of mesothelioma claims to the UK insurance industry between 2004 and 2040 are summarised below:

Table A1: 2004 summary of projections

| Undiscounted <br> Projection <br> of numbers | Low | Inflation |  |
| :---: | :---: | :---: | :---: |
| Low | $£ 3.0 \mathrm{bn}$ | $£ 3.8 \mathrm{bn}$ | High |
| Medium | $£ 3.6 \mathrm{bn}$ | $£ 4.4 \mathrm{bn}$ | $£ 5.9 \mathrm{bn}$ |
| High | $£ 4.0 \mathrm{bn}$ | $£ 5.0 \mathrm{bn}$ | $£ 6.6 \mathrm{bn}$ |

## Appendix A

Table A2: 2004 summary of selections

| Discounted at $5 \%$ (roughly the yield on ten year gilts at the time of the paper) |  |  |  |
| :---: | :---: | :---: | :---: |
| Projection <br> of numbers | Low | Medium | High |
| Low | $£ 1.5 \mathrm{bn}$ | $£ 1.8 \mathrm{bn}$ | $£ 2.1 \mathrm{bn}$ |
| Medium | $£ 1.7 \mathrm{bn}$ | $£ 2.0 \mathrm{bn}$ | $£ 2.5 \mathrm{bn}$ |
| High | $£ 1.9 \mathrm{bn}$ | $£ 2.2 \mathrm{bn}$ | $£ 2.7 \mathrm{bn}$ |

In estimating the future cost to the UK insurance industry from mesothelioma claims the working party made assumptions relating to:

1) The number of future mesothelioma claims; and
2) The level of compensation payable for each claim.

The table below details the key selections made in the previous working party's mesothelioma estimates.

Table A3: 2004 summary of assumptions

| Estimate | HSE model (Non- <br> clearance) | Average claim <br> costs for 2003 |  <br> court inflation) |
| :---: | :---: | :---: | :---: |
| Low | $\mathrm{k}=2.0$ | $£ 50 \mathrm{k}$ | $4 \%$ and $4 \%$ |
| Medium | $\mathrm{k}=2.6$ | $£ 50 \mathrm{k}$ | $4 \%$ and $6 \%$ |
| High | $\mathrm{k}=3.0$ | $£ 50 \mathrm{k}$ | $4 \%$ and $8 \%$ |

We will discuss each of these assumptions in more detail below.

## Appendix A

## Future number of mesothelioma claims

The estimates used the 2003 HSE model to project the future number of mesothelioma claims. The low, medium and high future claim projections were all scaled to the same level of claims, 1,422, in 2004. The past number of mesothelioma claims included nil claims.

The graph below shows the low, medium and high projections of the future number of mesothelioma claims, together with the actual historical claims from the data collected through the survey carried out by the working party.

Figure A1: 2004 projected number of Mesothelioma deaths

The low and high estimates were based on the 2003 HSE projections of the future number of mesothelioma deaths, but used a different $k$ factor, (exponent of time, modelling the increase of the risk of developing mesothelioma with increasing time from exposure): $\mathrm{k}=2$ and $\mathrm{k}=3$ respectively. The medium future claim projections used the HSE selected value for k of 2.6.

The working party's future claim projections used the HSE non-clearance model, which assumes that the asbestos fibres do not leave the lungs once they are inhaled.

The exposure used in these claim projections incorporated "background" exposure to asbestos (this means that there is exposure to asbestos after 1990, long after asbestos ceased being imported into the UK). The claim projections were then cut-off at 2040 as it was believed that the majority of claims reported after 2040 were expected to have been caused by background environmental exposures, which were unlikely to be covered by insurance contracts. The 2004 working party also felt that should the industry-sharing agreements continue in their then present forms up to 2040, some of the liability for these claims could relate to future periods of insurance and would therefore fall outside of the working party's scope.

## Appendix A

The table below summarises the key assumptions underlying the 2004 working party's projections of the future number of mesothelioma claims to the UK insurance industry.

Table A4: 2004 summary of key assumptions

| Estimate | Low | Medium | High |
| :--- | :---: | :---: | :---: |
| Nil claims | Included | Included | Included |
| Starting level | 1,422 | 1,422 | 1,422 |
| HSE Model used | non-clearance - <br> background" <br> exposure | non-clearance - <br> "background" <br> exposure | non-clearance <br> "background" <br> Cut-off point |
| K factor | 2040 | 2040 | exposure |
| Peak year | 2.0 | 2.6 | 2040 |
| Peak number of | 2009 | 2013 | 3.0 |
| claims | 1,489 | 1,610 | 2015 |
| Total future | 37,914 | 43,492 | 1,727 |
| claims |  |  | 47,777 |

## Average cost of mesothelioma claims

The 2004 working party selected a market average cost for mesothelioma claims that was mid-way between the actual average cost from the data collected through the survey of the UK insurance industry and their fitted average cost curve. The graph below details the actual average incurred cost and the fitted average cost together with the selected starting average cost. The chart below includes nil claims.

Figure A2: 2004 projection of average mesothelioma cost

An exponential curve was fitted using regression analysis, which gave a reasonable fit, apart from the last four years. It was suggested that this slow down in the average cost of mesothelioma claims in the last four years was due to a couple of possibilities:

- Under-reserving of claims on these recent years.
- A change in the trend of average costs.

## Appendix A

The 2004 working party believed that a combination of the two factors might be the most likely as the graph suggested that the rate of increase in the average cost has been slowing over the past ten years.

It was expected that the underlying mesothelioma costs would start to decrease, as the average age of claimants would become older (with lower compensation amounts for loss of earnings or future care). This is discussed in more detail in the next Section.

## Inflation for mesothelioma claims

The 2004 working party considered the award to mesothelioma claimants to be comprised of the following components:

- A fixed cost component; and
- An age-related component.

In order to determine the future cost of mesothelioma claims, they used an average cost model that assessed the future expected average cost, taking into account:

- Court inflation on the fixed component; and
- Wage inflation as well as the increase in the average age of claimants in the agerelated component.

The graph below details the low, medium and high future mesothelioma average cost per claim in future years. All the scenarios assumed that wage inflation was $4 \%$ p.a. with court inflation of $4 \%, 6 \%$ and $8 \%$ p.a. respectively.

## Appendix A

Figure A3: 2004 inflation assumptions

The overall inflation rate starts lower and tends towards the court inflation. This effect is in part due to the dampening impact of the increasing average age of claimants.

From one year to the next the average age of mesothelioma claimants increases by less than a whole year. Initially, the wage-related component of an average mesothelioma award makes up the greater proportion of the claim; therefore the inflation on the wage-related component of the award increases at less than $4 \%$ p.a. Eventually, as claimants get older, the fixed part of the claim makes up the majority of the award and the inflation rate tends to increase towards the assumed level of court inflation.

## Claims per death

To derive the number of different insurers against which an individual makes a claim (and hence the ratio of the number of claims to the number of deaths), the working party looked at the difference between:

- their selected average cost per claim (based on the data they had collected); and
- the estimated $100 \%$ indemnity costs provided by several companies.

In order to compare the two, they had to remove nil claims and legal expenses from their selected average cost.

The following two tables detail the 2004 working party assumptions on the proportion of claims that settle at nil costs and the proportion of legal expenses per claim for each disease type.

## Appendix A

Table A5: 2004 assumptions re nil claims and legal expenses

| Disease type | Working Party 04 <br> selected ACPC <br> (includes nils) | Proportion of <br> claims settled at nil <br> cost | Working Party 04 <br> selected ACPC <br> (excludes nils) |
| :--- | :---: | :---: | :---: |
| Mesothelioma | $£ 50,000$ | $20 \%$ | $£ 62,500$ |
| Asbestosis | $£ 17,000$ | $20 \%$ | $£ 21,250$ |
| Lung cancer | $£ 38,000$ | $20 \%$ | $£ 47,500$ |
| Pleural | $£ 11,000$ | $20 \%$ | $£ 13,750$ |
| plaques/thickening |  |  |  |
|  | Working Party 04 | Proportion of legal | (excludes legal |
| Disease Type | selected ACPC |  |  |
| (excludes nils) | costs | expenses and nils) |  |
| Mesothelioma | $£ 62,500$ | $15 \%$ | $£ 53,125$ |
| Asbestosis | $£ 21,250$ | $15 \%$ | $£ 18,063$ |
| Lung cancer | $£ 47,500$ | $15 \%$ | $£ 40,375$ |
| Pleural | $£ 13,750$ | $30 \%$ | $£ 9,625$ |
| plaques/thickening |  |  |  |

These figures were then compared to the average $100 \%$ indemnity costs that various companies had supplied. The average costs by each disease type are detailed in the table below.

Table A6: 2004 average costs by disease type

| Disease type | ACPC <br> (excludes legal <br> expenses and nils) | Estimated average <br> 100\% indemnity <br> costs | Ratio |
| :--- | :---: | :---: | :---: |
| Mesothelioma | $£ 53,125$ | $£ 108,222$ | 2.0 |
| Asbestosis | $£ 18,063$ | $£ 45,222$ | 2.5 |
| Lung cancer | $£ 40,375$ | $£ 115,000$ | 2.8 |
| Pleural | $£ 9,625$ | $£ 12,491$ | 1.3 |

* The working party combined the pleural plaques and pleural thickening claims together by assuming that $90 \%$ of these claims were pleural plaques.

A reasonable proportion of people who make asbestos-related claims would have periods of employment with asbestos exposure at more than one company. A separate claim would then be made to the insurer of each of these companies. Hence the 2004 working party expected the average company share of a claim to be lower than the $100 \%$ claim amount.

Taking this into account, the working party selected a ratio of 2.5 for all asbestos-related claims; which suggested that each claimant makes a claim with, on average, 2.5 insurance companies. They noted that this ratio was fairly consistent across the non-pleural diseases. The working party suggested that the observed lower ratio on pleural plaques/thickening claims might be due to the different characteristics of those claims.

The working party noted that using a ratio of 2.5 implied that, for mesothelioma claims, only a third of those currently dying from mesothelioma were making an insurance claim. They assumed that there was no change in the future proportion of people making an insurance claim and that if this proportion were to increase going forward, then their estimates would be understated.

## Appendix A

## Previous lung cancer estimates

The previous working party's low, medium and high estimates, for the cost of lung cancer claims to the UK insurance industry between 2004 and 2040 are summarised below:

Table A7: 2004 lung cancer estimates

| Undiscounted <br> Projection <br> of numbers | Low | Inflation |  |
| :---: | :---: | :---: | :---: |
| Low | $£ 39.4 \mathrm{~m}$ | Medium | High |
| Medium | $£ 117.8 \mathrm{~m}$ | $£ 137.4 \mathrm{~m}$ | $£ 46.0 \mathrm{~m}$ |
| High | $£ 211.7 \mathrm{~m}$ | $£ 266.2 \mathrm{~m}$ | $£ 165.8 \mathrm{~m}$ |

| Discounted at 5\% (roughly the yield on ten year gilts at the time of the paper) |  |  |  |
| :---: | :---: | :---: | :---: |
| Projection |  | Inflation |  |
| of numbers | Low | Medium | High |
| Low | $£ 29.8 \mathrm{~m}$ | $£ 31.7 \mathrm{~m}$ | $£ 34.0 \mathrm{~m}$ |
| Medium | $£ 67.8 \mathrm{~m}$ | $£ 76.6 \mathrm{~m}$ | $£ 88.5 \mathrm{~m}$ |
| High | $£ 98.7 \mathrm{~m}$ | $£ 116.9 \mathrm{~m}$ | $£ 144.2 \mathrm{~m}$ |

## Future number of lung cancer claims

The graph below shows the low, medium and high projections of the future number of lung cancer claims, together with the actual historical claims from the data collected through the survey carried out by the working party.

Figure A4: 2004 projected number of lung cancer claims

## Appendix A

The working party observed that the number of claims had been showing a downward trend over the past fifteen years. The low projection assumed that the trend would continue in a linear fashion. The high projection assumed that the trend was the same as for the medium estimate of future mesothelioma claim numbers (i.e. the 2003 HSE projection). The medium projection was in between the two and assumed that the current number of claims continued for a period and then tailed-off. The working party highlighted that one of the biggest uncertainties affecting the number of lung cancer claims was the possibility of lawyers targeting all lung cancer claims, most of which will be smoking related. The working party did not consider this in their projections.

## Previous asbestosis estimates

The previous working party's low, medium and high estimates, for the cost of asbestosis claims to the UK insurance industry between 2004 and 2040 are summarised below:

Table A8: 2004 asbestosis estimates

| Undiscounted <br> Projection <br> of numbers | Low | Inflation <br> Medium | High |
| :---: | :---: | :---: | :---: |
| Low | $£ 448.7 \mathrm{~m}$ | $£ 545.1 \mathrm{~m}$ | $£ 672.8 \mathrm{~m}$ |
| Medium | $£ 568.1 \mathrm{~m}$ | $£ 712.9 \mathrm{~m}$ | $£ 912.3 \mathrm{~m}$ |
| High | $£ 823.4 \mathrm{~m}$ | $£ 1,087.3 \mathrm{~m}$ | $£ 1,471.0 \mathrm{~m}$ |
|  |  |  |  |
| Discounted at 5\% (roughly the yield on ten year gilts at the time of the paper) |  |  |  |
| Projection |  | Inflation |  |
| of numbers | Low | Medium | High |
| Low | $£ 312.2 \mathrm{~m}$ | $£ 364.3 \mathrm{~m}$ | $£ 429.8 \mathrm{~m}$ |
| Medium | $£ 371.3 \mathrm{~m}$ | $£ 443.0 \mathrm{~m}$ | $£ 536.2 \mathrm{~m}$ |
| High | $£ 486.6 \mathrm{~m}$ | $£ 601.9 \mathrm{~m}$ | $£ 759.1 \mathrm{~m}$ |

## Appendix A

## Future number of asbestosis claims

The graph below shows the low, medium and high projections of the future number of asbestosis claims, together with the actual historical claims from the data collected through the survey carried out by the working party.

Figure A5: 2004 projected number of asbestosis claims

The working party commented that unlike mesothelioma, which can allegedly be caused by a single asbestos fibre, it requires a reasonable exposure to asbestos in order to develop asbestosis. They therefore expected a much earlier peak in the number of asbestosis claims, due to the earlier reduction in heavy asbestos exposure through the introduction of tighter regulations.

The various projections were based on the working party's "high level model". The medium projection assumed that the number of claim notifications were approximately at the peak at that time. The high curve assumed that asbestosis claims continued to rise until 2008 and the low curve assumed that they were already past the peak and asbestosis claim numbers were firmly on their way down.

## Appendix A

## Previous pleural plaques/thickening estimates

The previous working party's low, medium and high estimates, for the cost of pleural plaques/thickening claims to the UK insurance industry between 2004 and 2040 are summarised below:

Table A9: 2004 pleural plaques/thickening estimates
Undiscounted

| Projection <br> of numbers | Low | Inflation <br> Medium | High |
| :---: | :---: | :---: | :---: |
| Low | $£ 212.9 \mathrm{~m}$ | $£ 223.3 \mathrm{~m}$ | $£ 234.2 \mathrm{~m}$ |
| Medium | $£ 714.9 \mathrm{~m}$ | $£ 763.4 \mathrm{~m}$ | $£ 815.2 \mathrm{~m}$ |
| High | $£ 1,193.7 \mathrm{~m}$ | $£ 1,302.8 \mathrm{~m}$ | $£ 1,423.1 \mathrm{~m}$ |

Discounted at 5\% (roughly the yield on ten year gilts at the time of the paper)

| Projection <br> of numbers | Low | Inflation <br> Medium | High |
| :---: | :---: | ---: | ---: |
| Low | $£ 199.4 \mathrm{~m}$ | $£ 208.6 \mathrm{~m}$ | $£ 218.3 \mathrm{~m}$ |
| Medium | $£ 641.6 \mathrm{~m}$ | $£ 682.7 \mathrm{~m}$ | $£ 726.5 \mathrm{~m}$ |
| High | $£ 1,018.8 \mathrm{~m}$ | $£ 1,105.3 \mathrm{~m}$ | $£ 1,200.0 \mathrm{~m}$ |

## Future number of pleural plaques/thickening claims

The graph below shows the low, medium and high projections of the future number of pleural plaques/thickening claims, together with the actual historical claims from the data collected through the survey carried out by the working party.

Figure A6: 2004 projected number of pleural plaques / thickening claims

## Appendix A

The working party stated that this was the most difficult projection due to the extremely high numbers of claims seen in the past few years. They saw the big question to be whether or not insurers were about to see an upwards blip in claims as had been seen in the US, or whether the pleural plaques test cases would nip the issue in the bud and see claims drop right off, both in number and cost.

## Summary of previous assumptions for non-mesothelioma claims

The table below details the key selections made in the previous working party's nonmesothelioma estimates.

Table A10: 2004 non-mesothelioma projection assumptions

| Disease type | Average <br> claim costs <br> for 2003 | Low | Inflation <br> Medium | High |
| :--- | :---: | :---: | :---: | :---: |
| Lung Cancer | 38,000 | Wage $=4 \%$, | Wage $=4 \%$, | Wage $=4 \%$, |
| Asbestosis | 17,000 | Court $=4 \%$ | Court $=6 \%$ | Court $=8 \%$ |
| Pleural plaques/thickening | 11,000 | $1 \%$ | $3 \%$ | $5 \%$ |

The previous working party used the data they collected through the survey of the UK insurance industry to derive their selected average costs and inflation assumptions as shown in the graph below.

Figure A7: 2004 non-mesothelioma average costs

## Appendix A

The working party used the same low, medium and high inflation assumptions for lung cancer claims as they derived for mesothelioma claims; see Section 2.1.3 for more details on the mesothelioma inflation assumptions. They based this decision on the following:

- The average cost of lung cancer claims had increased substantially over time and had a similar pattern to the average cost of mesothelioma claims;
- A fitted exponential curve to the average cost of lung cancer claims implied a rate of inflation that was similar to that implied for mesothelioma claims; and
- There are similar opinions regarding how older claimants could cause average costs to plateau in the future.
For asbestosis and pleural plaques/thickening claims, the working party assumed inflation rates of $1 \%, 3 \%$ and $5 \%$ for their low, medium and high estimates, respectively. The medium assumption was based around the observed inflation in both asbestosis and pleural plaques claims over the last decade.

## Appendix B:

- Data Collection Process and Templates

## Appendix B - Data Collection Template

## Asbestos Working Party II - Data Collection Template (2008 Year-End Update)

1. We have deliberately asked for a large number of data items, and acknowledge that most companies will not be able to provide every data item. However, please provide as much data as you can. In particular, we are most interested in mesothelioma claims, so getting more detailed information for these claims would be of most benefit.
2. Ideally all figures should be extracted at 31 December 2008. However if this is not possible please clearly indicate the extraction date.
3. In all the sheets, "unidentified asbestos related" refers to claims for which you are unable to distinguish which asbestos-related disease they relate to, but know that they are an asbestos-related claim. Alternatively, if you are able to distinguish mesothelioma and non-mesothelioma claims only, please fill in the columns "mesothelioma" and "total non-mesothelioma".
4. A number of the sheets refer to "low value" claims. This term has been used to describe those claims that have been settled at a non-zero cost below a pre-defined threshold of $£ 1,000$ per claim.
5. Please indicate for each notification or settlement year on each completed sheet whether you believe the data entered to be "reliable and consistent" (column K). Clearly this is a fairly subjective question. For instance you may believe that data for notification years before 1995 is partially incomplete, based on a different data source or processes, and therefore subject to greater uncertainty or reduced credibility, and therefore can not be compared to years post 1994. In this case you would enter ' $Y$ ' in years from 1995-2008 only.
6. Each individual sheet gives more detail on exactly what data we are collecting, but if you are unsure on any of the definitions, please contact Matt Wilde on the Asbestos Working Party via 01603683883 / wildem@norwich-union.co.uk who can help clarify what data is required
7. Please return completed forms to Peter Stirling at the Institute of Actuaries at peter.stirling@actuaries.org.uk by 31 March 2009. Peter will be responsible for collating the responses to provide back to the Working Party for analysis.
8. Only direct claims should be included (i.e. no reinsurance claims) and all monetary amounts should be your own company share only (i.e. exclude amounts covered by other insurers).
9. Please ensure any "total" columns sum to the individual components that make-up the total.

## 10. Many thanks for your participation!

## Appendix B - Data Collection Template

| NUMBER OF CLAIMS NOTIFIED BY NOTIFICATION YEAR |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Notification Year | Pleural Plaques | Asbestosis | Asbestos Related Lung Cancer | Pleural Thickening | Total NonMesothelioma | Mesothelioma | Total Identified Asbestos Related | Total Unidentified Asbestos Related | Total | Reliable and Consistent? ( $\mathrm{Y} / \mathrm{N}$ ) |
| 1990 1991 1992 1993 1994 1995 1996 1997 1998 1999 2000 2001 2002 2003 2004 2005 2006 2007 2008 |  |  |  |  |  |  |  |  |  |  |
| Total |  |  |  |  |  |  |  |  |  |  |

Notes
Please provide the number of claims (nil and non-nil) notified to your company for each notification year, split by disease-type. Total Non-Mesothelioma = Pleural Plaques + Asbestosis + Asbestos Related Lung Cancer + Pleural Thickening Total Identified Asbestos Related = Total Non-Mesothelioma + Mesothelioma

## Appendix B - Data Collection Template

NUMBER OF CLAIMS SETTLED AT TRUE NIL COST (E0) BY NOTIFICATION YEAR

| NUMBER OF CLAIMS SETTLED AT TRUE NIL COST (£0) BY NOTIFICATION YEAR |  |  |  |  |  |  |  |  |  | Reliable and Consistent? ( $\mathrm{Y} / \mathrm{N}$ ) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| :--- | :--- |

| AVERAGE SHARE OF CLAIM PAID BY INSURER BY NOTIFICATION YEAR |  |  |  |  |  |  |  |  |  | Reliable and Consistent? (Y/N) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Notification Year | Pleural Plaques | Asbestosis | Asbestos Related Lung Cancer | Pleural Thickening | Total NonMesothelioma | Mesothelioma | Total Identified Asbestos Related | Total Unidentified Asbestos Related | Total |  |
|  <br> 1990 <br> 1991 <br> 1992 <br> 1993 <br> 1994 <br> 1995 <br> 1996 <br> 1997 <br> 1998 <br> 1999 <br> 2000 <br> 2001 <br> 2002 <br> 2003 <br> 2004 <br> 2005 <br> 2006 <br> 2007 <br> 2008 |  |  |  |  |  |  |  |  |  |  |
| Total |  |  |  |  |  |  |  |  |  |  |

Notes
Please provide the average share of the claimants total award met by your company by notification year
This should only refer to the shares of different primary insurers / companies and should exclude any amounts ceded to reinsurers
E.g. if a claim is split as follows.

E30,000 your company
£20,000 Insurer B
£50,000 Government
The share \% would be 30\%

## Appendix B - Data Collection Template

| AVERAGE INITIAL YEAR OF CLAIMANT EXPOSURE BY NOTIFICATION YEAR |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Notification Year | Pleural Plaques | Asbestosis | Asbestos Related Lung Cancer | Pleural Thickening | Total NonMesothelioma | Mesothelioma | Total Identified Asbestos Related | Total Unidentified Asbestos Related | Total | Reliable and Consistent? (Y/N) |
|  <br> 1990 <br> 1991 <br> 1992 <br> 1993 <br> 1994 <br> 1995 <br> 1996 <br> 1997 <br> 1998 <br> 1999 <br> 2000 <br> 2001 <br> 2002 <br> 2003 <br> 2004 <br> 2005 <br> 2006 <br> 2007 <br> 2008 |  |  |  |  |  |  |  |  |  |  |

Notes
Please provide the average year in which the claimant was first exposed to asbestos by notification year
In the case of multiple exposure periods, please only consider the first relevant period
If the information available only relates to your own period of cover please use this data, but if possible please base it on the first year exposed even if you are not covering this period
E.g. if a claimant was exposed from 1950 to 1955, and your company provided cover from 1953 to 1955, please base the data on "1950" rather than "1953"

Also, please indicate if your company only wrote EL insurance before and/or after certain years. E.g. if your company went into run-off for EL insurance in 1975.

## Appendix B - Data Collection Template

| Data As At: |  |
| :--- | :--- |

| AVERAGE AGE OF CLAIMANT AT NOTIFICATION BY NOTIFICATION YEAR |  |  |  |  |  |  |  |  |  | Reliable and Consistent? ( $\mathrm{Y} / \mathrm{N}$ ) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Notification Year | Pleural Plaques | Asbestosis | Asbestos Related Lung Cancer | Pleural Thickening | Total NonMesothelioma | Mesothelioma | Total Identified Asbestos Related | Total Unidentified Asbestos Related | Total |  |
|  <br> 1990 <br> 1991 <br> 1992 <br> 1993 <br> 1994 <br> 1995 <br> 1996 <br> 1997 <br> 1998 <br> 1999 <br> 2000 <br> 2001 <br> 2002 <br> 2003 <br> 2004 <br> 2005 <br> 2006 <br> 2007 <br> 2008 |  |  |  |  |  |  |  |  |  |  |
| Total |  |  |  |  |  |  |  |  |  |  |

Notes
Please provide the average age of claimants at notification by notification year where date of birth of claimant is available
Please give a rough indication of the $\%$ of claims for which this data is available

## Appendix B - Data Collection Template

## Notes

Please provide the number of claims recorded in each age band for each notification year
Please only record mesothelioma claims. Totals should match to mesothelioma claims recorded in sheet 1)

## Appendix B - Data Collection Process

## Schedule 1

## PROCESS DOCUMENTATION FOR ASBESTOS WORKING PARTY PER CLAIM DATA

## COLLECTION MARCH 2009

## 1. INTRODUCTION

1.1 The UK Actuarial Profession, which comprises the Faculty of Actuaries and the Institute of Actuaries, performs research into General Insurance Issues and a number of working parties are formed by members of the UK Actuarial Profession. The working parties are advertised by the UK Actuarial Profession and are open to any member who is interested to join. The working parties present their findings at the General Insurance Research Organisation (GIRO) Conference each year.
1.2 In 2007, an Asbestos Working Party (AWP) has been formed, and intends to be in existence until the end of 2009. The AWP is proposing to set up a per claim asbestos data collection for insurance companies represented on the working party.
1.3 The companies represented on the working party and who will participate in the data collection are as follows: Royal Sun Alliance, Norwich Union, Zurich Insurance Plc, AXA, Equitas, EIROS, Chester Street and Builders Accident (represented by PwC).

## 2. PER CLAIM INFORMATION TO BE PROVIDED BY PARTICIPANTS

2.1 The information provided by each participant will relate to only claims arising due to asbestos exposure. The information collected is only for all asbestos related claims notified from 2003 onwards and relates to the following categories:
(a) Cover type (e.g. EL / PL);
(b) Claim ID (e.g. meso, asbestos related lung cancer, asbestosis, pleural thickening and pleural plaques);
(c) Trade code AWP (as per instructions set out in spreadsheet Per Claim Template 2009.xls);
(d) Trade Code OWN (as per instructions set out in spreadsheet Per Claim Template 2009.xls);
(e) Insured first year indicator (year the insured first notified a meso claim, yyyy);
(f) Date reported (dd/mm/yyyy or blank if not known);
(g) Date settled (dd/mm/yyyy or blank if not known or not settled);
(h) Claimant exposure start year (yyyy or blank if not known);
(i) Date of birth year (yyyy or blank if not known);
(j) $\operatorname{Sex}(\mathrm{M}$ or F or blank if not known)
(k) Total claim paid (in $£ \mathrm{~s}$ ); and
(l) Total case estimate (in £s)
2.2 The data will be as at $31^{\text {st }}$ December 2008

## Appendix B - Data Collection Process

## 3. DATA COLLECTION PROCESS

3.1 Information provided by the AWP members will be put into an Excel spreadsheet, one line per claim using the headings, in order, as given and defined in Section 2.1, and sent to Peter Stirling of the Institute of Actuaries. A template with an example format has been provided - see Per Claim Template 2009.xls.
3.2 Peter Stirling will collect and amalgamate the data sent by the AWP members into one dataset using Excel. This dataset will be sorted by trade code, so that the individual datasets can not be determined when the total dataset is viewed.
3.3 Peter Stirling will keep one copy of the original submission and create another copy fropm which the Trade code OWN field will be deleted. It is this copy of the data that will be provided to the AWP to use as detailed below.
3.4 From the original copy the two trade code lists will be copied to another spreadsheet and a mapping table (Trade code OWN to Trade code AWP) will be created with the help of the AWP.
3.5 Peter Stirling will keep the datasets on a secure PC within the Institute of Actuaries.
3.6 The working party members will be able to perform an analysis on the dataset, but will not be able to take a copy of the amalgamated data set away from the Institute.
3.7 The working party members will be able to have the results of analyses e-mailed to them by Peter Stirling.
3.8 Only the results of relevant data analyses will be published in the report (GIRO paper) as submitted to the Institute of Actuaries. The data itself will not be made publicly available.
3.9 Following the completion of the research by the AWP, Peter Stirling will delete all the datasets held by the Institute.

## Schedule 2

## ASBESTOS WORKING PARTY MEMBERS

Peter Taylor<br>Robert Brooks<br>Gregory Overton<br>Graham Sandhouse<br>Matthew Ball<br>Brian Gravelsons<br>Andy Whiting<br>Charlie Kefford<br>Darren Michaels<br>Dan Sykes<br>Dan Beard<br>Stephen Robertson-Dunn<br>Patrick Nolan<br>Jerome Schilling<br>John Wilson<br>Emiliano Ruffini<br>Naomi Coachman<br>Matthew Wilde

## Appendix B - Data Collection Template

## Asbestos Working Party - Per Claim Template (2008 Year-End Update)

The following fields for each claim notifiedpost $\mathbf{3 1 / 1 2 / 2 0 0 2}$ to $\mathbf{3 1 / 1 2 / 2 0 0 8}$ should be filled in or left blank if there is no data
If the claim is known to have settled, but no settlement date has been recorded then a date of $31 / 12 / 9999$ should be used.
The examples have been correctly formatted and give an example of some of the expected field values.
Explanation of the Insured First Year can be found in sheet Insured First Year
Trade Code AWP should be derived using the instructions provided in the sheet Trade Codes
One sheet should be completed and then e-mailed to Peter Stirling - peter.stirling.actuaries.org.uk

| Cover Type | Claim ID | Trade Code AWP | Trade Code OWN | Insured First Year | Date Reported | Date Settled | Claimant Exposure Start Year | Year of Birth Sex | Total Claim Paid | Total Case Estimate |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| EL | Meso | Boiler related |  | 2003 | 31/03/2006 | 31/03/2007 | 1963 | 1929 M | 100,000.00 | 100,000.00 |
| PL | Pleural Plaques | Carpenter |  | 2004 |  | 31/12/9999 |  | F |  |  |
|  | Pleural Thickening | Construction |  | 2005 |  |  |  |  |  |  |
|  | Asbestosis | Direct asbestos exposure |  | 2006 |  |  |  |  |  |  |
|  | Asbestos Related Lung Cancer | Electrician |  | 2007 |  |  |  |  |  |  |
|  | Unidentified Non-Meso | Fitter |  |  |  |  |  |  |  |  |
|  |  | Lagger / Insulator |  |  |  |  |  |  |  |  |
|  |  | Maintenance |  |  |  |  |  |  |  |  |
|  |  | Manufacturing |  |  |  |  |  |  |  |  |
|  |  | Marine |  |  |  |  |  |  |  |  |
|  |  | Miscellaneous |  |  |  |  |  |  |  |  |
|  |  | Plumbing |  |  |  |  |  |  |  |  |
|  |  | Transport |  |  |  |  |  |  |  |  |

## Appendix C:

- Working Party Models

## Appendix C - Working Party Models

The following models have been developed by the Working Party and can be obtained from the Actuarial Profession's website together with this paper in a zipped file: Asbestos Working Party 2009 Models. Each spreadsheet model contains documentation and instructions on how the spreadsheet works.

## AWP Mesothelioma Population Projection Model (see section 4.4)

This spreadsheet replicates the methodology used by the HSE/ HSL, and contains the selected Working Party projections.

## Simple Birth Cohort Model (see section 4.3)

This spreadsheet uses a birth cohort approach to project future mesothelioma deaths.

## Latency Model (see section 4.2)

This spreadsheet uses the latency model approach to project future mesothelioma deaths.

## Mesothelioma Average Cost Model (see section 6)

This spreadsheet sets out how the mesothelioma claimant cost is modelled.

## Claimant Ratio Derivation (see section 5)

This spreadsheet outlines how the claimant ratios are derived.

## Appendix D:

- Summary of Mesothelioma Projection Results

## Appendix D: AWP Mesothelioma Projection 2009

Scenario outputs

|  |  |  |  | Results for 2009 and post deaths |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Scenario Number | Population Deaths | Claimant to death ratio (CD ratio) | Inflation | Male GB Population Deaths | UK Insurance Claims ${ }^{60,893}$ | UK Insurance Cost (£m) |
| 1 | HSL model | AWP 1: Stays constant at 2008 level | RPI $=1.5 \%$ | Male G8 Population Deaths 55 |  |  |
| 2 | HSL model | AWP 1: Stays constant at 2008 level | $\mathrm{RPI}=2.5 \%$ | 55,878 | 60,893 | 10,424 |
| 3 | HSL model | AWP 1: Stays constant at 2008 level | RPI $=3.5 \%$ | 55,878 | ${ }^{60,893}$ | 13,118 |
| 4 | HSL model | AWP 2: Proportionate increases for 10 years, eligible ratio to $75 \%$ in 10 years | $\mathrm{RPI}=1.5 \%$ | 55,878 | 68,201 | 9,319 |

# Appendix D: AWP Mesothelioma Projection 2009 

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio
Inflation (RPI):

$$
\begin{aligned}
& \text { HSL } 2009 \\
& \text { AWP 1: Stays constant at } 2008 \text { level } \\
& 3.50 \%
\end{aligned}
$$

# Appendix D: AWP Mesothelioma Projection 2009 

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio:
Inflation (RPI):
HSL 2009
AWP 3: Pro
AWP 3: Proportionate increases for 50 years, eligible ratio to $75 \%$ in 10 years
2.50\%

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio:
Inflation (RPI):
HSL 2009
AWP 4: Pro
AWP 4: Proportionate increases for 10 years, max eligible ratio reached by oldest band too
2.50\%

# Appendix D: AWP Mesothelioma Projection 2009 

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio:
Claim to death ra
Inflation (RPI):
HSL 2009
AWP 5: Max (assuming 100\% propensity) reached linearly by 2013
2.50\%

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio:
Inflation (RPI):

$$
\begin{aligned}
& \text { AWP selected population model } \\
& \text { AWP 1: Stays constant at } 2008 \text { level } \\
& 2.50 \%
\end{aligned}
$$

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio:
Inflation (RPI):
AWP selected population model
AWP 2: Proportionate increases for 10 years, eligible ratio to $75 \%$ in 10 years
2.50\%

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio
Inflation (RPI):
AWP selected population model
AWP selected population model
AWP 4: Proportionate increases for 10 years, max eligible ratio reached by oldest band too
$1.50 \%$

# Appendix D: AWP Mesothelioma Projection 2009 

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio
Inflation (RPI):
AWP selected population model
AWP 5: Max (assuming $100 \%$ propensity) reached linearly by 2013
$1.50 \%$

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Popula to death ratio
Inflation (RPI):

$$
\begin{aligned}
& \text { Latency Model } \\
& \text { AWP 1: Stays constant at } 2008 \text { level } \\
& 1.50 \%
\end{aligned}
$$

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio:
Inflation (RPI):

$$
\begin{aligned}
& \text { Latency Model } \\
& \text { AWP 3: Proportionate increases for } 50 \text { years, eligible ratio to } 75 \% \text { in } 10 \text { years } \\
& 3.50 \%
\end{aligned}
$$

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:

Population Deaths:
Claim to death ratio
Inflation (RPI):
Latency Model
AWP 4: Proport
AWP 4: Proportionate increases for 10 years, max eligible ratio reached by oldest band too
3.50\%

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio
Inflation (RPI):

> Initial Birth Cohort Model AWP 1: Stays constant at 2008 level $2.50 \%$

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio
Inflation (RPI):

> Initial Birth Cohort Model AWP 2: Proportionate increases for 10 years, eligible ratio to $75 \%$ in 10 years $2.50 \%$

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio
Inflation (RPI):

> Initial Birth Cohort Model AWP 3: Proportionate increases for 50 years, eligible ratio to $75 \%$ in 10 years $2.50 \%$

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio:
Inflation (RPI):

> Initial sirth Cohort Model AWP 4: Proportionate increases for 10 years, max eligible ratio reached by oldest band too 2.50\%

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio
Inflation (RPI):

> Initial Birth Cohort Model AWP 5: Max (assuming $100 \%$ propensity) reached linearly by 2013 $2.50 \%$

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio
Inflation (RPI):

Alternative Birth Cohort Model
AWP 2: Proportionate increases for 10 years, eligible ratio to $75 \%$ in 10 years

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio
Inflation (RPI):

Alternative Birth Cohort Model
AWP 2: Proportionate increases for 10 years, eligible ratio to $75 \%$ in 10 years

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio:
Inflation (RPI):

Alternative Birth Cohort Model
AWP 3: Proportionate increases for 50 years, eligible ratio to $75 \%$ in 10 years

## Appendix D: AWP Mesothelioma Projection 2009

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio:
Inflation (RPI):
Alternative Birth Cohort Model
AWP 4: Proportionate increases for 10 years, max eligible ratio reached by oldest band too

# Appendix D: AWP Mesothelioma Projection 2009 

Key Assumptions:
Population Deaths:
Population Deaths:
Claim to death ratio
Inflation (RPI):

> Alternative Birth Cohort Model AWP 5 Max (assuming $100 \%$ propensity) reached linearly by 2013 $1.50 \%$

## Appendix G:

- British Population Projections

## G1 Background and Summary

## Importance of Population Projections

Estimated future numbers of mesotheliomas and other asbestos-related diseases are affected by the projected number of subjects at risk of developing the disease, unless the estimates are based on pure extrapolation from past data or directly linked to some past indices (e.g. as in our latency model). The HSE model and the birth-cohort model arrive at their estimates of future male mesothelioma deaths by applying estimated mortality rates (at by age and period, or age and cohort) to the projected number of persons alive at selected ages in all future years.

Population projections are uncertain, and different assumptions will lead to different estimates of future mesothelioma deaths. The original AWP 2004 (and HSE 2005) mesothelioma projections used the so-called 2001-based population projections produced by the Government Actuary's Department (GAD). ${ }^{1} \quad$ The AWP 2009 and HSE 2009 projections use the updated 2006-based projections, which are now produced by the Office of National Statistics (ONS).

In both cases, the principal projections were used. We also tested the impact of alternative projections, both in terms of assumed mortality (including the impact of alternative assumptions about future improvements) and assuming no future net migration.

## Impact on Mesothelioma Projections

While the fact mesothelioma projections would be affected by different underlying population assumptions was always known, it is probably fair to say that the degree of their sensitivity was not fully appreciated and that the impact of moving to the more recent 2006-based projections came as a bit of a surprise. In fact, we showed in section 4 that about half the increase in the future projected deaths from the HSE 2005 to the HSE 2009 parameterised models is due to the change in population assumptions. Indeed, the HSE 2005 model and the AWP 2009 preferred parameterisation produce similar forecasts if the same 2006 -based GB population projection is used.

As discussed in more detail below, most of the impact of the updated projections is due to lower actual (to 2006) and projected mortality rates for the cohorts born in the 1923-1940 years. The number of projected mesothelioma deaths is much less sensitive to assumptions about long term mortality improvement rates for other cohorts. Finally, changes in population due to past and projected net migration to the UK seem to have minimal impact on the projected number of mesothelioma deaths.

## G2 2001 - Based Projections

The GAD (until 2005) and the ONS (since 2006) have produced population projections by age and sex for the United Kingdom and constituent countries every two years. In some years, interim projections are also produced. The 2001-based projection was such an interim projection, using the same long term assumptions as the 2000-based projection but with starting mortality rates updated to the 2001 rates.

[^17]
## Appendix G-British Population Projections

## Methodology

Population projections rely on a number of demographic assumptions, including fertility rates and net migration figures. Since most mesothelioma cases develop at older ages and asbestos exposure dramatically decreased after 1980, the most important assumptions for our purposes relate to initial and projected mortality rates. The latter are not directly estimated, rather they are derived by applying selected rates of mortality improvement.

In this respect, the general methodology of adopted by the GAD and then ONS has been to select initial mortality rates from the most recent interim population and mortality tables at the time of the projection - in this instance these were the 2001 interim tables. Initial rates of mortality improvements are derived from recent experience and then assumed to converge over time to a common long term rate. ${ }^{2}$ While detailed assumptions used have changed in the last decade, this approach, used by many other national statistical offices, has been maintained. It is interesting to note that, although with several differences in the details, the prototype mortality projection model recently proposed by the Continuous Mortality Investigation (CMI) group of the actuarial profession also has a similar structure.

## High level assumptions

Future mortality rates were derived by applying projected improvement rates to the initial 2001 interim mortality table by sex and single year of age. The initial rates of improvement were taken from the observed (smoothed) improvement rates between 2000 and 2001, which were then assumed to decrease to the long term target rate of $0.75 \%$ per annum by 2025 , which is assumed to halve thereafter every ten years (i.e. $0.375 \%$ in 2035 etc.) The transition was not assumed to occur linearly, but more rapidly in the earlier years.

The higher improvement rates observed for the generations (cohorts) born around 1931 were assumed to continue, but at a slower rate than in the past and to also converge to an annual $0.75 \%$ by $2025 .{ }^{3}$

## Cohort life expectancies

The following table summarises projected cohort life expectancies at various ages attained in specified years. These are the life expectancies implied by the projected life tables, including improvements. E.g. the projected life expectancy of a 40 year old in 2010 is derived applying the survival rate of a 40 year old in 2010, that of a 41 year old in 2011 and so on. These life expectancies provide a synthetic measure of the projected mortality levels of the underlying tables.

| 2001 based principal |  |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: |
|  |  |  |  |  |  |
| (GB) Males |  |  |  |  |  |
| Age $/ \mathbf{Y r}$ | $\mathbf{2 0 1 0}$ | $\mathbf{2 0 2 0}$ | $\mathbf{2 0 3 0}$ | $\mathbf{2 0 4 0}$ |  |
| $\mathbf{4 0}$ | 40.5 | 40.9 | 41.3 | 41.7 |  |
| $\mathbf{5 0}$ | 30.9 | 31.3 | 31.7 | 32.0 |  |
| $\mathbf{6 0}$ | 21.9 | 22.3 | 22.7 | 23.0 |  |
| $\mathbf{7 0}$ | 14.0 | 14.5 | 14.8 | 15.1 |  |
| $\mathbf{8 0}$ | 7.8 | 8.4 | 8.6 | 8.8 |  |
| $\mathbf{9 0}$ | 4.1 | 4.4 | 4.6 | 4.7 |  |

[^18]
## G3 2006 - Based Projections

## High level assumptions

The 2006-based projections had similar assumptions to the 2001-based projections, with the following main differences:

- Actual mortality improvements in 2001-2006 were higher than assumed in the 2001 principal projection (closer to the high life expectancy variant). These were reflected in lower mortality rates in the 2006 interim table and in higher initial improvement rates.
- The long term target rate of improvement was increased from $0.75 \%$ to $1 \%$ per year.
- Most importantly, since those born in the 1923-1940 period continued to display higher mortality improvements compared to other cohorts, with no evidence of a decline in the differentials, it was assumed that they would continue to experience higher improvements in the future as well, by up to $1.5 \%$ more per year for those born in $1931 .{ }^{4}$

The 2006-based ONS principal projections imply rates of future mortality improvement that are now more broadly in line (although perhaps a bit lower) with those commonly assumed by many UK life actuaries in commercial (pricing and reserving) calculations.

Of the above changes in assumptions from 2001, it is the third that has had by far the strongest impact on mesothelioma death projections. This is due to the large degree of coincidence between the generations most affected by the above mentioned mortality improvement "cohort effect" and those from whose ranks the largest numbers of future mesothelioma deaths are expected to arise. In fact, about one half of UK meso sufferers projected to die in the next 20 years are expected to be born between 1923 and 1940, and the vast majority of the remaining future mesothelioma sufferers is expected to have been born after 1940.

It is important to note that, although experience from other countries suggests that the mortality improvement "cohort effect" is likely to persist for many years, this is by no means certain, and it is quite possible that future mortality developments may be significantly different from current expectations. As demonstrated by the impact of moving to the more recent 2006-based projections, this may significantly affect the future number of mesothelioma deaths.

## Cohort life expectancies

The cohort life expectancies implied by the 2006-based projections for British males are as follows:

| (GB) Males |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Age / Yr | 2010 | 2020 | 2030 | 2040 |
| 40 | 44.8 | 46.0 | 47.1 | 48.3 |
| 50 | 34.6 | 35.7 | 36.8 | 37.9 |
| 60 | 25.2 | 26.2 | 27.2 | 28.2 |
| 70 | 16.7 | 17.7 | 18.5 | 19.3 |
| 80 | 9.0 | 10.5 | 11.2 | 11.8 |
| 90 | 4.3 | 5.1 | 5.9 | 6.3 |

[^19]
## G4 - Comparison of 2001- and 2006-Based Projections

The cohort life expectancies at the older ages are significantly higher for the 2006-based projections than they were in the 2001-based projections. This is particularly visible for those born in the 1923-1940 "cohort-effect" period. For example, the life expectancy of 1930 born males, who will be 80 in 2010, is over one year or $15 \%$ higher using the 2006-based tables than the 2001-based projections. The life expectancy of males born in 1940, who will be 70 years old in 2010, has increased by over 2.5 years or almost $20 \%$.

The following graph compares the relative cohort life expectancies between 2006- and 201based projections at selected ages and intervals. One can see the particularly rapid increase in the life expectancy differences at age 80 (until 2020) and age 90 (until 2030), which reflects the cumulative impact of the higher mortality improvements of the 1923-1940 cohorts, where of course those born in 1940, the last years of these cohorts, will be aged 80 in 2020 and 90 in 2030.

British Males Cohort Life Expectancies: 2001 vs 2006 based GAD/ONS Principal Projections

Another way of looking at the projections is to compare the projected period life expectancies. These are the life expectancies that may be derived by assuming the (actual or estimated) mortality rates reached in a certain year will continue to be applicable without further changes, and are a common synthetic measure of mortality levels at different ages.

The following table synthesizes the period life expectancies projected to be achieved in different periods - we included the latest 2008 based projections (discussed in the last section) as in this case the 2008 values reflect the actual interim table.

Period life expectancies under alternative projection bases

| 2001 based principal (GB) Males |  |  |  | 2006 based principal |  |  | 2008 based principal |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  |  |  |
| Age / Yr | 2008 | 2015 | 2025 | 2008 | 2015 | 2025 | 2008 | 2015 | 2025 |
| 40 | 38.1 | 39.0 | 39.8 | 39.2 | 41.0 | 42.7 | 39.0 | 41.2 | 43.0 |
| 50 | 28.9 | 29.8 | 30.6 | 30.1 | 31.8 | 33.5 | 29.8 | 31.9 | 33.8 |
| 60 | 20.4 | 21.2 | 21.9 | 21.5 | 23.2 | 24.8 | 21.3 | 23.3 | 25.0 |
| 70 | 13.0 | 13.7 | 14.3 | 13.9 | 15.5 | 17.0 | 13.7 | 15.6 | 17.2 |
| 80 | 7.3 | 7.9 | 8.3 | 7.8 | 8.9 | 10.3 | 7.7 | 9.0 | 10.4 |
| 90 | 3.9 | 4.1 | 4.4 | 3.9 | 4.4 | 5.2 | 3.8 | 4.5 | 5.3 |

The absolute differences in life expectancies are lower, of course, because they only reflect shorter periods of mortality improvement. However, one can see that the 2006-based projections imply much faster improvements - the period life expectancies in 2008 are already higher than those projected to be achieved only in 2015 using the 2001-based assumptions. In other words, the combination of higher actual and projected rates of improvement imply that between 2001 and 2008 mortality rates improved almost twice as fast as expected. The period life expectancies derived from the 2008 interim table used in the newly published 2008-based projections are slightly lower than those implied by the 2006-based projections, however the projected future life expectancies are slightly higher.

## G5 - Net Migration

Population projections are affected by assumptions about population inflows and outflows, i.e. migration. Since these projections affect mesothelioma death estimates in principle the latter may be distorted if the people entering and/or leaving the country have, on average, significantly different asbestos exposure history. Insurance claims projections may be further distorted if the propensity or anyway ability to present claims new entrants and leavers is different from expected.

The UK has seen significant net immigration in the last two decades, so in principle this might cause some distortions in mesothelioma projections. For example, over one million males moved into the UK between 1991 and 2007. ${ }^{5}$ However, closer examination of actual estimates of net migration flows reveals that net inflows into the UK are limited to people of age 44 or younger. For ages 45-59/64, the statistics show a net outflow over the period of about 70,000 people, with a small cumulative outflow of nearly 10,000 people of age 60/65 and higher.

The ONS assumes that flows of a similar magnitude and sign will continue to occur in their 2006- and 2008-based projections, notably an annual net outflow of about 15,000 males for ages 50 and higher. The 2001-based projections made similar, if slightly lower assumptions.

Since mesothelioma projections only depend on population figures at older ages, and males born after 1960 contribute extremely little to projections, we would expect that net migration assumptions of the magnitude just described would have only a small impact on the projections.
5 See National Statistics information on total international migration at
http://www.statistics.gov.uk/STATBASE/Product.asp?vInk=15053, particularly table 2.07 by age and sex. http://www.statistics.gov.uk/STATBASE/Product.asp?vInk=15053 , particularly table 2.07 by age and sex.

## Appendix G-British Population Projections

In fact, we estimated the impact of stripping out migration figures by overlaying actual and projected survival rates onto the actual population in a selected year and projecting forward. The impact on mesothelioma projections was a very small increase in projected deaths, with results little affected by the initial selected year. We tried a number of different years from 1985 onwards, with results ranging from essentially no change if 1985 is selected to an increase of about $0.5 \%$ in mesothelioma deaths if 2008 is chosen.

These results were initially somewhat surprising, however they are perfectly consistent with our models of mesothelioma deaths given actual and projected population outflows at older ages.

Of course, if future migration patterns changed materially and differed significantly from expectations, this could distort the projections, especially of deaths leading to potential insurance claims, as discussed in section 4.4.

## G6 - Addendum: 2008 - Based Projections

At the end of October 2009, the ONS produced a new set of mortality projections, the 2008based projections, followed by the publication of additional variants in November 2009.

The following table summarises the cohort life expectancies implied by the new projections.

| 2008 based principal |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: |
| (GB) Males |  |  |  |  |
| Age $/$ Yr $\mathbf{2 0 1 0}$ $\mathbf{2 0 2 0}$ $\mathbf{2 0 3 0}$ $\mathbf{2 0 4 0}$ <br> $\mathbf{4 0}$ 45.2 46.4 47.5 48.6 <br> $\mathbf{5 0}$ 34.9 36.1 37.2 38.2 <br> $\mathbf{6 0}$ 25.4 26.5 27.4 28.4 <br> $\mathbf{7 0}$ 16.9 17.9 18.8 19.6 <br> $\mathbf{8 0}$ 9.1 10.7 11.4 12.0 <br> $\mathbf{9 0}$ 4.3 5.2 6.0 6.4 |  |  |  |  |

These are slightly higher than those implied by the 2006-based projections, although as mentioned the actual mortality rates in 2008 were slightly higher than expected.

We have quickly tested the impact that the updated population projections would have on future mesothelioma deaths estimates. Using either our preferred parameterisation or HSE's 2009 parameterisation, the new population projections would imply a very small increase in projected mesothelioma deaths of less than 1\%.

## Appendix H :

- Comparison Between GB Mesothelioma Deaths Projections

## Appendix H-Comparison between GB male mesothelioma deaths projections:

|  |  |  |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |

## Notes

The deaths are for males aged between 20 and 89.
The peak number of deaths outlined in the HSL report in 2016 is 1,990 for ages 20 to 89 as per Table 6.
The HSE 2003/5 numbers based on the non-clearance with background exposure assumption.
The HSL 2009 Report numbers have been taken from the HSL 2009 Report.
The HSL 2009 (AWP Projection Model) are based on the fminsearch parameter estimates for Model A as per Table 4 in the HSL report.
Differences occur due to the use of the median parameter values.
The median projection as set out in the HSL paper doesn't necessarily coincide with the set of median parameter values.
