## So which algorithm is best?

- All algorithms are biased in some manner.
- The **“No Free Lunch Theorem”**: no algorithm is best over all problems.
- Methods may work well for a certain class of problems.
- Best result may be an aggregate of methods.
- In other words, **“it depends”**. Human judgement is required.

## Issues for insurers

- New data sources – implications for better models:
  - Telematics for motor insurance.
  - Fraud detection via social media – several examples to date, but can it be automated?
  - Some health insurers are pricing based on health related data.
- More powerful algorithms:
  - Can GLM's keep up? Can new algorithms give a competitive advantage?
- How could London Market insurers gain from these techniques?

## Issues for actuaries

- Will actuaries be replaced by machines/computer scientists?
- Human judgement is required - technically and statistically trained actuaries are well placed.
- Do actuaries need to train?
  - E.g., CAS Institute accreditation in data science.
