Reserving in the Pressure Cooker

- Solvency II embedding
- Timescales and pressures on the Reserving Actuary
- No surprises reserving
- Deterministic vs stochastic methods
- Automation survey
- Machine Learning
- Questions
Solvency II embedding
Solvency II embedding

- Technical Provisions Issues
- Increased detail and submission vs 2015
- RSR with heavy reliance for actuarial teams
- Board signalling/no surprises
- Push to complete Pillar III projects
- Actuarial Function Reports
Solvency II embedding (2)

- Solvency II vs Bermuda vs Swiss
- Discounted Reserves vs Undiscounted Reserves
- 1 year view of reserve variability vs Ultimate view of reserve variability
Solvency II embedding (2)
Timescales and pressures on the Reserving Actuary
Great pressure exists:

- On the reserving process caused by demand for faster and earlier close processes along with ‘no surprises’ for management
- For deep dives with relevant management information and controls information from the reserving processes to enhance operational controls over business
- Reduction in time available for actual insight into reserving position - automation required to accelerate timings
- Soft market leads to added scrutiny by all (e.g. Management, underwriters and regulators)
- Optimal processes should be both efficient and add value.

Sample timetable:
Timescales and pressures

Timing

- Early close with Roll forward
- 2018 Lloyd’s reporting deadlines reduced by one week
- Process required to be moved earlier by one month - different dates? Benefits?
- SII ~ GAAP ~ Finance
- Time and iterations
- Increased familiarity and understanding of new requirements with time

Quality

- Do tighter timescales lead to reduced quality?
- Capital models push more diversification; more classes needs more time for modelling
- Perfect storm – tight deadlines and new / increased regulation
- Hopefully only temporary!
- Automation?
- Machine reserving?
No surprises reserving
No surprises for whom?

- Board or lower level committees (e.g. Reserving / UW committee)?
- What is the materiality level of a ‘surprise’?
- Pre agreed actions?
No surprises reserving

Managing stakeholders through the process

- When to cut data – balance date? Previous quarter? Early close and true up?
- AvE - how often? When to flag to stakeholders?
- Discuss observed trends
- Highlight potential changes and impact (e.g. Ogden)
- Presentation to Reserve Committee in advance of booking numbers
No surprises for whom?

Managing stakeholders through the process

Closer Relationships

- Closer to losses / included in discussions to minimise surprises
- Pricing / Reserving / Capital / Planning feedback loops
- Understand the business and how mix is changing
- Stress and scenario test - potential events and impact / reaction if they occur
- Watchlists for potential claims (and probability)

No surprises reserving
Deterministic vs stochastic reserving
Deterministic BEL vs. Stochastic Reserving

**Deterministic Best Estimate Reserves**
- GAAP Reserving
- Combination of projections and methods – average or single chain ladder scenario

**Stochastic Mean Reserves**
- Internal model Reserve risk.
- Stochastic – usually bootstrap. Many simulations; some not all together realistic

- Purpose (e.g. Point estimate, reserve ranges or full distribution)
- Segmentation and homogeneity of data
- Data volumes - Reliability of stochastic projections
- User selection – significant expert judgment, expertise of reserving Actuary
## Reserving Diagnostics, Reserve Risk Aspects

Automation
Automation survey

Your reserving process – and embedded automation

Reinsurance netting down

Reporting automation including Solvency II

IFRS automation based on work to date

Opportunity or threat

Automation vs offshoring

19 September 2017
Survey results

- Data quality often poor and requires processing
- Currently considerable amount of manual work in the reserving process
- Opportunity for automation in report generation
- Machine learning an option when enough data but skills and costs a barrier
- IFRS seen as an impetus for automation
- Opportunity to minimise errors, work faster and allow more time for analysis
Machine Learning
Machine Learning overview

- Popularity of machine learning driving innovation
- Can Machine Learning be used for reserving?
- Reduce information loss and improve insight
- Uptake limited by trade off of simplicity vs accuracy
- Companies now investigating different predictive techniques to mitigate the Mean Absolute Error (MAE)
- Machine learning ‘blackbox’ like but different machine learning methods which we can use:
  1. GBM (Gradient Boosting Machine)
  2. Decision Tree (the random forest)
  3. LASSO (least absolute shrinkage and selection operator)
A proposed METHOD

The errors in the reserving estimates (over or under reserving) can be reduced by using machine learning; but more importantly...

One emerging view is that the errors in the reserving estimates can be explained much better by using machine learning on granular claims data.

The classical reserving methods use a one-size-fits-all approach, so it is difficult to learn from the actual vs expected. Machine learning could give insight here

Example:
If you use a single cumulative development factor for all bodily injury claims for the year 2016, the A vs E would not tell you which cohorts of injuries developed worse than expected.

Machine learning models use the claims and exposure features which affect the development, frequency and severity.

Simply put, machine learning would use algorithms to estimate a different development factor for brain injury vs muscle injury.

Parameter estimation involves learning from historical granular data, minimising the errors and back-testing the parameters.

It therefore allows for a more in-depth analysis of the actual vs expected, e.g. brain injuries may have deteriorated worse than expected

Although machine learning models are computationally intensive and complex, they can be implemented very easily once built.

Importantly, they can be rerun frequently within small intervals (say monthly) to monitor the actual vs expected.

One suggestion from the working party is not for machine learning to replace the traditional reserving techniques, but rather to validate and enhance them.

Importantly, in this case machine learning models should be used to understand and explain the actual vs expected, and over time, help to develop more granular assumptions for traditional models such as loss ratios, development factors, frequency and severity.

</tbody>
</table>

Comments

- Triangle = has lowest Absolute error but suffers higher mean error
- Forest = has slightly higher absolute error but very low mean error
- GBM = has lowest mean error but very high absolute errors, see predictions which are very sticky around mean mark
- Lasso regression = performs worst due to linear effect of the model, cannot capture the non-linear trends in the data
Machine Learning overview

Comparison of methods

Commentary

- Employer’s Liability Bodily Injury
- Large losses are not capped, large loss is >100K
- Prediction Error is (Actual - Expected)/Expected
- Total Claims 4815, split into 3972 Training 843 Tested (for prediction error check performance)
- Variables used - Incurred, Paid, Case, Type of Injury, Part of Body, State
